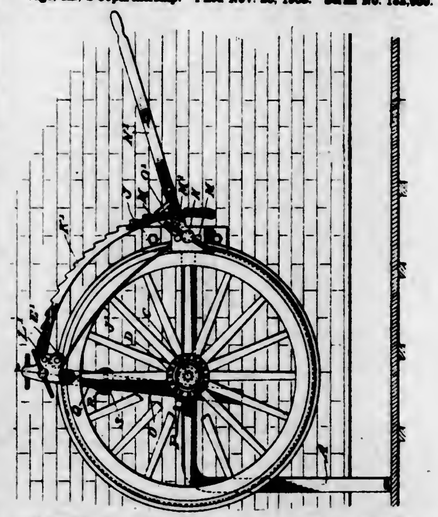
17. An injector-burner comprising a body provided with an oilway and two discharge slots or ducts extending angularly with respect to said way, said oilway communicating directly into the primary duct, a partition above said primary duct over which said way communicates into the secondary duct, and a steamway discharging right angularly across the planes of said discharge-ducts, said body provided with a lip extending beyond the point of discharge from said steamway and spaced apart from the edge or end of the walls of the primary oil-discharge duct, the end of the outer wall of said duct terminating above the plane of the top wall of the steam-discharge slot and the end of the outer wall of said secondary duct terminating above the plane outer wall of said primary duct.

18. An injector-burner comprising a body provided with an oilway, two oil-discharge slots or ducts and a steamway, said ducts discharging right angularly across the plane of discharge from said steamway, the end of the outer wall of the inner duct terminating above the plane of the upper edge of the steamway and the outer wall of the outer duct terminating above the plane of the edge of said outer wall of said inner duct to provide for the upward expansion of the steam from the steamway.

19. An injector-burner comprising a body provided with oil and steam ways, two oil-discharge ducts and a steam-discharge slot, the lower wall of the steam-discharge slot extended outwardly across the plane of the inner duct, the outer wall of the inner duct terminated above the plane of the upper edge of the discharge-slot.

20. An injector-burner comprising a body provided with oil and steam ways, two oil-discharge ducts, and a steam-discharge slot, the lower wall of the steam-discharge slot extended outwardly across the plane of the inner duct, the outer wall of the inner duct terminated above the plane of the discharge-slot, and the outer wall of the outer duct terminated above the plane of the end of said outer wall of said inner duct.

811,936. **APPARATUS FOR APPLYING TIRES TO WHEELS.** AXEL R. LE MOON, Chicago, Ill., assignor to Nelson & Le Moon, Chicago, Ill., a Copartnership. Filed Nov. 25, 1903. Serial No. 182,089.



Claim.—1. In a tire-applying device, a wheel-support, means for clamping the wheel against rotary movement upon its rotary support, an arm pivotally mounted concentric with the wheel-support, a bracket carried by said arm and including jaws, deflecting-rollers carried by said jaws and arranged to engage underneath the unapplied portions of the tire-binding wires, said bracket being pivotally mounted upon said arm for rocking adjustment relative thereto, means for clamping said bracket in adjusted position, whereby the peripheral surfaces of said rollers may be brought substantially flush with the edges of the flanges of the wheel-channel, and means for rocking said arm, as and for the purpose set forth.

2. In a tire-applying device, a supporting-frame, a stud carried thereby and arranged to extend through the hub of a wheel to support the same, means for clamping the wheel against rotary movement upon said stud, an arm pivotally mounted upon said stud, a bracket pivotally mounted upon said arm for rocking adjustment relative thereto and including jaws, means for clamping said bracket in adjusted position, means for moving said jaws toward and from each other, guide-rollers carried by said jaws and arranged to rest upon the edges of the flanges of the wheel-channel, deflecting-rollers also mounted upon said jaws and in inclined relation with respect to the planes of said flanges, said deflecting-rollers being arranged to engage underneath the unapplied portions of the tire-binding wires, and means for rocking said arm, as and for the purpose set forth.

811,937. CLOSET-TANK. FRANK H. LEMMERMANN, Columbus, Ohio, assignor to The Columbus Brass Company, Columbus, Ohio, a Corporation of Ohio. Filed June 8, 1905. Serial No. 264,894.

Claim.—A tank, comprising a wooden shell, an unattached sheet-metal lining for the bottom and inner sides of said shell, means on said shell for holding the upper edge of said lining with freedom of vertical movement in respect to the said shell and holding means, and space between said upper edge and confining means for said vertical movement.

811,938. GRAIN-HANDLING APPARATUS. ELMER H. LOGAN, Larned, Kans. Filed Mar. 3, 1905. Serial No. 248,357.

Claim.—1. The combination of a portable supporting-frame, a carrying-frame mounted on said supporting-frame and adjustable longitudinally of the same, an elevator mounted on the said carrying-frame with its ends projecting beyond the sides of the supporting-frame, and means for adjusting the elevator vertically upon the carrying-frame.

2. The combination of a carrying-frame, a vertically-adjustable elevator carried thereby, standards at one end of the elevator, a drag pivotally supported upon said standards, and means for simultaneously operating the drag and the elevator.

3. In an apparatus of the character described, the combination of a movable supporting-frame having curved slots which terminate at their opposite ends at opposite sides of the longitudinal center of said frame, and an elevator extending through said supporting-frame and having trunnions engaging the slots thereof, and provided at its receiving end with a caster to rest upon the ground.

4. In an apparatus of the character described, the combination of a movable supporting-frame having curved slots which terminate at their opposite ends at opposite sides of the longitudinal center of said frame, an elevator extending through said supporting-frame and having trunnions engaging the slots thereof, and provided at its receiving end with a caster to rest upon the ground, and means for moving said trunnions upward or downward in said slots.

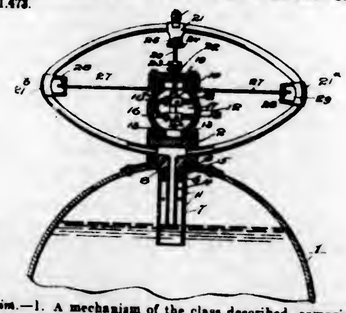
5. In an apparatus of the character described, the combination of a movable supporting-frame having curved slots which terminate at their opposite ends at opposite sides of the longitudinal center of said frame, an elevator extending through said supporting-frame and having trunnions engaging the slots thereof, and provided at its receiving end with a caster to rest upon the ground, means for moving said trunnions upward or downward in said slots, and means for securing said trunnions at the desired point of adjustment in said slots.

6. In an apparatus of the character set forth, the combination of a head-box having a side arranged to depend therefrom, an elevator having vertically-arranged converging wings which form a hopper with the pendent side of the header-box, and a drag arranged to project into the header-box and feed the material therein to the hopper.

7. In an apparatus of the character described, the combination of a movable supporting-frame, an elevator supported from and projecting beyond the sides of said frame and adjustable longitudinally thereof, a header-box, an endless drag pivotally supported from the elevator, and means for yieldingly swinging the drag upward or downward when projected into the header-box.

8. In an apparatus of the character set forth, the combination of a supporting-frame having curved slots in its sides, an elevator extending through said frame and provided on its sides with trunnions engaging said curved slots, and means for moving the trunnions along the slots and securing them at any desired point.

811,939. FEED-WATER MECHANISM. WILLIAM LOUDON and JOHN J. HENDRICKS, Seattle, Wash. Filed Mar. 22, 1905. Serial No. 251,473.



Claim.—1. A mechanism of the class described, comprising a base member, provided with a three-way passage, an apertured, hollow member removably secured to said base member, an inner tubular member of less length than said apertured member removably secured to said base member, an elliptical, expansible tubing provided with right and left threaded surfaces formed upon its ends removably secured to said base member, a valve-casing secured to said base member, said valve-casing having an inlet and outlet opening, a movable valve positioned within said casing, yokes positioned upon said tubing at diametrically opposite points, adjustable stay-rods connecting said valve-casing and yokes, valved means secured to said tubing and providing direct communication between the interior of said tubing and the outer atmosphere, a valve-stem secured to said valve, said stem provided with an integral extension, and means for adjustably securing said valve-stem to said tubing.

2. A mechanism of the class described, comprising a base member provided with oppositely right and left threaded openings and a threaded opening formed at right angles to said openings, an inner tubing threaded into said right-angled opening, an apertured, outer tubing of greater length than said inner tubing removably secured to said base member, an elliptical tubing provided with right and left threaded surfaces formed upon its ends secured within said base member, a valve-casing removably secured upon said base member, a movable valve positioned within said valve-casing, a removable cap carried by said casing, said valve comprising members provided with depending legs, a stem secured to said valve and extending through said cap, adjustable rods secured to said casing, yokes connecting said rods to the narrowest portion of said ellipse, a valved vent formed upon said expansible tubing, and means for adjustably securing said stem to said expansible tubing.

3. In a mechanism of the class described, the combination of a base member, inner and outer tubular members secured to said base member, a valve-casing secured to said base member, a movable valve positioned within said casing, an elliptical, expansible member secured to said base member, and means connecting said expansible member to said valve.

4. In a mechanism of the class described, the combination of a base member, an inner and an outer apertured tubing secured to said base member, an elliptical expansible member secured to said base member, a valve-casing, a movable valve mounted therein, means connecting said valve with said expansible tubing, and means connecting said expansible tubing to opposite portions of said valve-casing.

5. In a mechanism of the class described, the combination with a boiler, of a base element secured to said boiler, means depending from said base element to the water-surface in said boiler, elliptical, expansible means secured to said base element, and valve means assembled with said base element and connected to said expansible means.

6. In a mechanism of the class described, the combination with a boiler, of a base element, depending, hollow members secured to said base element, an expansible member secured to said base element, a valve-casing secured to said base element, a valve mounted within said casing, adjustable means connecting said valve and expansible member, and laterally-extending means connecting said valve-casing and said expansible member.

7. In a mechanism of the class described, the combination with a boiler, of a base element removably positioned upon said boiler, a removable, inner tubing secured to said base element and extending downwardly in said boiler, an outer, apertured, removable tubing secured to said base element and extending downwardly in said boiler, said outer tubing of greater length than the inner tubing, a removable, expansible member secured to said base element, a valve, and adjustable means connecting said valve and expansible member.

8. In a mechanism of the class described, the combination with a boiler, of a single, looped expansible member carried by said boiler, an inner and an outer member carried by said boiler, one of said members in communication with said expansible member, said inner and outer members extending downward into the boiler, and valve means assembled with said expansible member.

9. In a mechanism of the class described, the combination with a boiler, of hollow members of different dimensions extending downwardly in said boiler, expansible means secured in a communicating position with said hollow members and carried by said boiler, a vent-valve secured to said expansible means, and valve means adjustably secured to said expansible means.

10. In a mechanism of the class described, the combination with a boiler, of hollow members extending into said boiler, one of said members provided with apertures, valve means, and means connected to said members and valve means for actuating said valve means.

11. In a mechanism of the class described, the combination with a boiler, of an inner and outer hollow member carried by said boiler, said outer member provided with an aperture, and valve-actuating means carried by said hollow members.

12. In a mechanism of the class described, the combination with a boiler, of members of different lengths extending into said boiler, and valve-actuating means connected with said members.

13. In a mechanism of the class described, the combination with a boiler, of removable members of different lengths positioned within said boiler, and valve-actuating means connected with said members.

14. In a mechanism of the class described, the combination with a boiler, of expansible means carried by said boiler, valve means coacting with said expansible means, and members, one inclosing the other, positioned within said boiler and extending to the water-column for permitting of the actuation of said expansible means when the water in the boiler has fallen below a predetermined level.

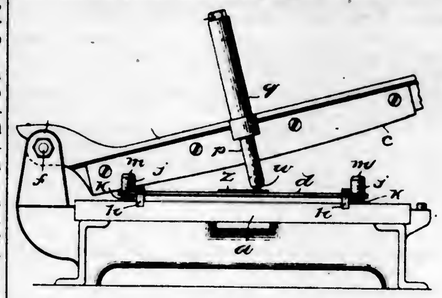
15. In a mechanism of the class described, the combination of a base element, a single looped, expansible member secured to said base element, valve means coacting with said member, and an inner and an outer member secured to said base element.

16. In a mechanism of the class described, the combination with a base element, of inner and outer members of different lengths secured to said base element, a looped, expansible member secured to said base element, and valve means coacting with said expansible member.

811,940. MACHINE FOR CUTTING SHEETS. CHARLES H. MARSTON, Reading, and ARTHUR P. HOLDEN, Malden, Mass., assignors to The National Shawmut Bank, Boston, Mass. Filed July 3, 1905. Serial No. 268,158.

Claim.—1. A cutting-machine comprising a table, a stationary blade, a clamp mounted on the table and yieldingly held away from the work-supporting surface thereof, a movable blade pivotally mounted with respect to the table, and means carried by the movable blade arranged to engage directly upon the clamp upon actuation of said movable blade and press and hold the same against the work while the latter is being cut.

2. A cutting-machine comprising a table, a shear-blade fixed thereto, a movable blade pivoted thereto in shearing relation with the fixed blade, a clamp supported near the work-supporting surface of the table, and a presser carried by the movable blade arranged to engage and travel along the clamp to press the clamp against the work while said movable blade is being actuated to cut the work.



3. A cutting-machine comprising a table, a shear-blade fixed thereto, a movable blade pivoted thereto in shearing relation with the fixed blade, a clamp supported near the work-supporting surface of the table, and a presser carried by and yieldingly projected from the movable blade arranged to engage and press the clamp against the work while said movable blade is being actuated to cut the work.

4. A cutting-machine comprising a table, a shear-blade fixed thereto, a movable blade pivoted thereto in shearing relation with the fixed blade, a clamp yieldingly held away from the work-supporting surface of the table, a presser carried by the movable blade and capable of moving relatively thereto and arranged to engage the clamp when the movable blade is brought into operative relation with the fixed blade, and means for yieldingly holding the presser in contact with the clamp.

5. A cutter comprising a table, a stationary shear-blade fixed thereto, an arm pivoted to the table, a shear-blade mounted on the arm, a guideway formed on the arm, a plunger movably held in the guideway, yielding means tending to project the plunger, and a clamp held above the surface of the table in position to be engaged by the plunger and pressed against the work supported on the table during the movement of the arm which brings the shear-blades into operative relation.

6. A cutter comprising a table, a stationary shear-blade fixed thereto, an arm pivoted to the table, a shear-blade mounted on the arm, a guideway formed on the arm, a plunger movably held in the guideway, yielding means tending to project the plunger, an anti-friction-roll carried by the plunger, and a clamp held above the surface of the table in position to be engaged by the roll on the plunger and pressed against the work supported on the table during the movement of the arm which brings the shear-blades into operative relation.

7. A cutting-machine comprising a table, a plate having a gaging edge located above and movable perpendicularly with respect to the work-supporting surface thereof, yielding means holding the plate separated from the table, shearing-blades arranged to trim the edge of a sheet supported on the table, and yielding means of greater power than the first said yielding means for pressing the plate against the sheet in opposition to said first yielding means when the sheet is being trimmed.

8. A cutting-machine comprising a table, cutting instrumentalities, guiding-studs mounted on the table adjacent said instrumentalities, a plate having a gaging edge for positioning the work located and guided by said studs, springs positioned by said studs normally holding the plate away from the table, and a spring-plunger for engaging and pressing the plate against the table when the cutting instrumentalities are operating.

811,941. CHLORATE-POWDER. CHARLES H. MATHEWS, Rio, Wis. Filed Sept. 9, 1905. Serial No. 277,706.

Claim.—1. The herein-described composition of matter comprising gasolene, spirits of turpentine, alcohol, water, sugar, and potassium chlorate, substantially as described.

2. The herein-described composition of matter composed of one part granulated sugar, one and one-half parts potassium chlorate, and enough of liquid composed of one part gasolene, one part spirits

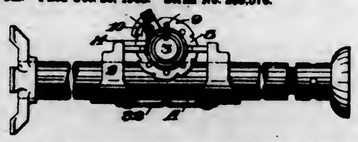
of turpentine, one part alcohol, and two parts water to moisten the mixture.

811,942. CIGAR FOR ASTHMA. AARON MENDELSOHN, San Francisco, Cal. Filed Aug. 21, 1905. Serial No. 275,142.

Claim.—1. A cigar or cigarette having the center formed of the stems and heads of stramonium and cherry-leaves inclosing or intertwining therewith to form a binder throughout the length of the stramonium filling serving as a binder therefor, and an exterior wrapper of tobacco-leaves.

2. An article of manufacture consisting of stramonium-stems clustered and disposed longitudinally to form a central filling, cherry-leaves inclosing or intertwined therewith a binder throughout the length of the stramonium filling serving as a binder therefor and an exterior wrapper of tobacco-leaves.

811,943. ROCK-BORING MACHINE. WILLIS C. MOORE, Los Angeles, Cal. Filed Oct. 20, 1905. Serial No. 283,576.



Claim.—1. A boring-machine comprising in combination a threaded spindle having means at one end for the attachment of a drill, a feed-nut on said spindle, a stationary support in which said nut is rotatably mounted, means for rotating the spindle, and means automatically operated by the spindle for turning the nut periodically in unison with the spindle.

2. A boring-machine comprising a threaded spindle having means at one end for the attachment of a drill, a feed-nut on said spindle, a support on which said nut is rotatably mounted, means for rotating the spindle, means for intermittently holding the nut against rotation, and automatically-operated means for releasing the nut and allowing it to turn at intervals in unison with the spindle.

3. The combination in a boring-machine, of a threaded spindle having means at one end for carrying a drill, a feed-nut on the spindle, a support on which said nut is rotatably mounted, means for rotating the spindle, means for holding the nut from turning, and means automatically operated by the spindle to release the nut from its locked position and allowing it to turn periodically in unison with said spindle.

4. The combination in a boring-machine, of a threaded spindle having means at one end for holding a drill, a feed-nut on the spindle, a support on which the nut is mounted to rotate, means for rotating the spindle, means for holding the nut against rotation, and means operated by the rotative movement of the spindle to release the nut and allow the nut and spindle to turn in unison.

5. The combination in a boring-machine, of a threaded spindle having means for carrying a drill, a nut on the spindle, a support in which the nut is mounted to rotate, means for rotating the spindle, means for holding the nut against rotation, and adjustable means automatically and intermittently operated by the spindle for releasing the nut to allow the latter to turn for longer or shorter periods in unison with the spindle.

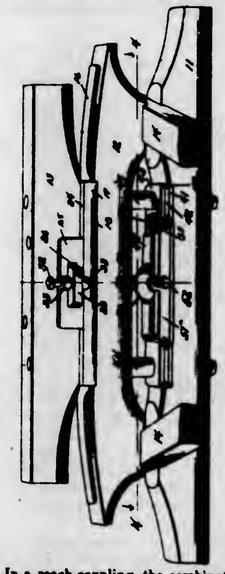
6. The combination in a boring-machine, of a threaded spindle having means for holding a drill, a feed-nut on the spindle, a support in which the nut is mounted to rotate, means for rotating the spindle, means for holding the nut against rotation, and adjustable means operated by the spindle to release the nut to allow it to turn periodically in unison with the spindle.

7. In a boring-machine, the combination of a threaded spindle having means for holding a drill, a feed-nut on the spindle, a support for the nut, said support having lateral segmental projections, and suitably-supported hook members engaging said projections to hold the drill to the work, said segmental projections loosely engaged over said hook members and permitting a limited oscillatory movement of the spindle, and means for rotating the spindle.

8. In a boring-machine, the combination of a threaded spindle having means for holding a drill, a feed-nut on the spindle, a support in which the feed-nut is mounted to rotate, means for rotating the spindle, a spring-pressed dog engaging the nut to hold the latter against rotation, a cam member turnable with and slidable lengthwise relative to the spindle, and means operated by the cam member to actuate the dog to release the nut.

9. In a boring-machine, the combination of a threaded spindle having means for holding the drill, a feed-nut on the spindle, a support in which the feed-nut is mounted to rotate, means for rotating the spindle, a spring-pressed dog engaging the nut to hold the latter against rotation, a cam member turnable with and slidable lengthwise relative to the spindle, means operated by the cam member to actuate the dog to release the nut, and means for varying the length of the period of the turning movement of the nut relative to a complete revolution of the spindle.

811,944. VEHICLE RUNNING-GEAR. GRANT MCHENRY, Mount Liberty, Ohio. Filed Apr. 11, 1905. Serial No. 254,994.



Claim.—1. In a reach-coupling, the combination with an axle having a socketed plate, of a reach having at its end a ball fitting in the socket, a retaining-plate over the ball, a block secured to the first-mentioned plate, and a set-screw threaded through said block and bearing on the retaining-plate.

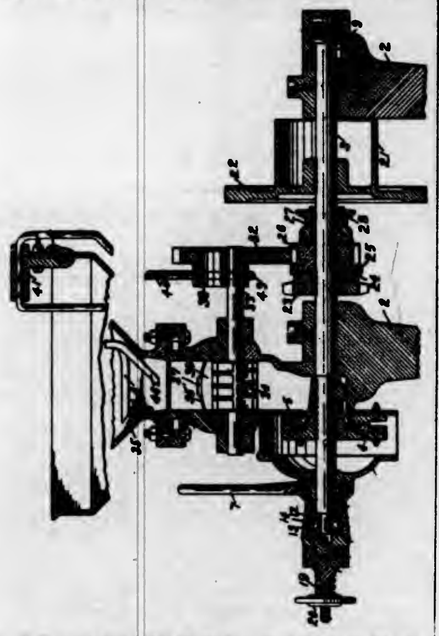
2. In a vehicle running-gear, the combination with a bolster having a socket and a transverse groove in its under side, of a sand-board having a projecting headed stud entering the socket, keys extending through the groove and having their inner ends shaped to fit the stud below the head, and means for securing the keys.

3. In a vehicle running-gear, the combination with a bolster having a socket and a transverse groove in its under side, of a plate secured to the bolster and having openings registering with the socket and groove, a sand-board having a projecting stud entering the socket, keys extending through the groove into engagement with the stud, and means carried by the aforesaid plate for securing the keys.

4. In a vehicle running-gear, the combination with a bolster having a socket and a transverse groove in its under side, of a wear-plate secured to the bolster and having openings registering with the socket and groove, a sand-board having a wear-plate provided with a projecting stud entering the socket, keys extending through the groove into engagement with the stud, and means carried by the first-mentioned plate for securing the keys.

811,945. GRINDING-MILL. CUNNINGHAM H. MCLAUGHLIN, Winona, Minn., assignor to New Winona Manufacturing Co., Winona, Minn., a Corporation of Minnesota. Filed Mar. 6, 1903. Serial No. 146,426.

Claim.—1. In a grinding-mill, the combination, with a fixed bur, of a longitudinally-movable shaft, a bur provided thereon and normally in cooperation with said fixed bur, a spring provided at one end of said shaft and normally tending to move said shaft lengthwise and separate said burs, a ball-bearing provided at the opposite end of said shaft to receive the thrust thereof, a housing or cage for said bearing, a yoke having a rocker bearing on said cage, springs connected with said yoke and arranged to overcome the tension of said first-named spring and hold said burs in grinding engagement with one another, and mechanism for relieving the pressure of said springs on said shaft to allow said first-named spring to move it lengthwise and separate said burs, substantially as described.



2. In a grinding-mill, the combination, with a fixed bur, of a longitudinally-movable shaft, a bur provided thereon and normally in cooperation with said fixed bur, a spring normally tending to move said shaft lengthwise and separate said burs, a ball-bearing provided at one end of said shaft to receive the endwise thrust thereof, a housing or cage for said bearing, a yoke having a central bearing on said cage, springs connected with ends of said yoke on each side of said bearing and arranged to overcome the tension of said first-named spring to hold said burs in grinding engagement with one another, and mechanism for relieving the pressure of said yoke-springs on said shaft to allow said first-named spring to move it lengthwise and separate said burs.

3. In a grinding-mill, the combination, with a frame and a fixed bur mounted thereon, of a longitudinally-movable shaft, a bur mounted on said shaft and movable therewith, a cage provided at one end of said shaft and comprising a cup 11 having an opening to receive the end of said shaft, and a plate 15 covering the open end of said cup and provided with a boss 16, a ball-bearing provided within said cup and adapted to receive the endwise thrust of said shaft, a spring-pressed yoke engaging said boss and normally tending to hold said burs together, and mechanism for relieving the pressure of said yoke on said boss and shaft to allow said burs to separate, substantially as described.

4. In a grinding-mill, the combination, with a frame and a hopper provided with a feed mechanism, of a fixed bur, a longitudinally-movable shaft, a bur mounted on said shaft and arranged to cooperate with said fixed bur, mechanism for moving said shaft lengthwise to separate said burs, a clutch-gear 23 secured on said shaft, a clutch member 25 arranged to move lengthwise on said shaft and engage said clutch-gear and having gear-teeth 26 in operative connection with said feed mechanism, a yoke 28 having rods 29 adjustably secured with said frame, and springs 30 provided on said rods 29, substantially as described.

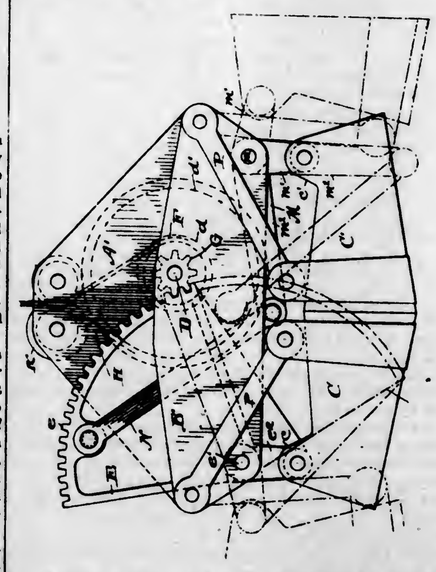
5. In a grinding-mill, the combination, with a frame and a hopper provided with a revolving feed mechanism, of a fixed bur, a longitudinally-movable shaft, a bur mounted thereon and arranged to cooperate with said fixed bur, a clutch mounted on said shaft and comprising a fixed and a movable member, said movable member having gear-teeth operatively connected with said feed mechanism, a spring-pressed yoke engaging said movable clutch member and normally tending to hold it in engagement with said fixed member, and mechanism for moving said shaft lengthwise to separate said burs, and said clutch member and simultaneously stop the grinding and feeding operation.

6. In a grinding-mill, the combination, with a frame and hopper, of a revolving feed mechanism provided with a gear 32 having an eccentric 39, a rod 40 adjustably mounted on said hopper and having a forked end to straddle said eccentric, and fingers at its opposite end which project horizontally across the discharge-opening in said hopper, for the purpose specified.

7. In a grinding-mill, the combination, with a frame and hopper, of a feed mechanism, a rod 40 mounted on said hopper and arranged to be oscillated vertically by the movement of said feed mechanism, and said rod having fingers arranged to project horizontally across the discharge-opening in said hopper and prevent the clogging of the material therein during the feeding operation, substantially as described.

8. In a grinding-mill, the combination, with a frame and hopper provided with a revolving feed mechanism having a gear 32, of a fixed bur, a longitudinally-movable shaft, a bur secured thereon and cooperating with said fixed bur, means for moving said shaft lengthwise to separate said burs, a clutch member 23 secured on said shaft, a movable clutch member 25 movable lengthwise on said shaft and having gear-teeth to engage the teeth of said gear 32, and a spring-pressed yoke engaging said movable clutch member and normally tending to hold it in engagement with said clutch member 23 but allowing them to separate when said shaft is moved lengthwise, substantially as described.

811,946. CLAM-SHELL BUCKET. JOHN MCMYLER, Cleveland, Ohio. Filed May 22, 1905. Serial No. 261,545.



Claim.—1. In a clam-shell bucket, the combination with the frame, and two bucket-jaws, of levers pivoted to opposite ends of said frame and having depending arms which are pivotally connected with the upper rear ends of the bucket-jaws, means for swinging said lever-arms to move their depending arms toward and from each other, and links P pivotally connected with the upper front parts of said bucket-jaws and with the frame at points above the rear ends of said jaws.

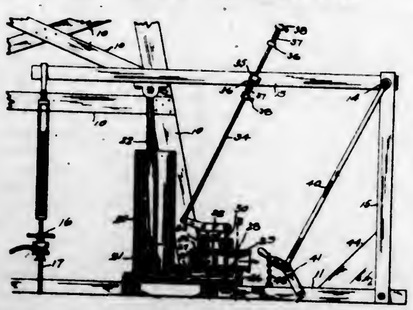
2. In a clam-shell bucket, the combination with the frame, and two bucket-jaws, of levers pivotally connected with the said frame

at opposite ends thereof and having depending arms which are respectively pivoted to the sides of the rear ends of said bucket-jaws, mechanism operating on the levers at one end of the frame to rock them back and forth, a link connecting the levers at one end of the frame with the levers at the other end of the frame and transmitting motion from one to the other, and links P pivotally connected with the sides of the front ends of said jaws and with the frame at points above the rear end of said jaws.

3. In a clam-shell bucket, the combination with the frame, and two bucket-jaws, of the levers E E mounted in the frame at one end thereof, and having depending arms which are pivotally connected with the rear end of one bucket-jaw, the bell-crank levers M, M mounted in the frame at the other end thereof and having depending arms which are pivotally connected with the rear end of the other bucket-jaw, means transmitting motion from the first-mentioned levers to said bell-crank levers, mechanism mounted in the frame for rocking the first-mentioned levers, and links P pivotally connected with the front ends of said bucket-jaws and with the frame at points above the rear ends of said jaws.

4. In a clam-shell bucket, the combination with the frame, and two bucket-jaws, of gear-segments mounted on alined axes in one end of the bucket-frame and having depending arms which are pivotally connected with the rear end of one bucket-jaw, a power-shaft mounted in the frame and carrying pinions engaging said segments, bell-crank levers M M mounted on alined axes in the other end of said frame and having depending arms which are pivotally connected with the rear end of the other bucket-jaw, links N connecting the horizontal arms of said bell-crank levers with the gear-segments, means for rotating the said power-shaft in either direction, and links P having their lower ends pivotally connected to the front ends of the bucket-jaws and having their upper ends pivotally connected with the frame at points above the rear ends of said bucket-jaws.

811,947. **WELL-DRILLING APPARATUS.** IRA L. NEELY, Independence, Kans. Filed Apr. 26, 1904. Serial No. 204,896.



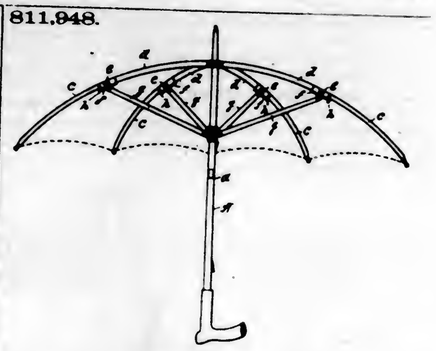
Claim.—1. A well-drilling apparatus including a walking-beam adapted to operate well-drilling tools, an upwardly-extending support to which said walking-beam is fulcrumed, said upwardly-extending support being fulcrumed at its lower end, means for moving said upwardly-extending support so as to give the beam longitudinal movement, and a stop to limit the longitudinal movement of said walking-beam.

2. A well-drilling apparatus including a foundation-frame, upwardly-extending posts pivoted at their lower ends to said foundation, a rod connecting the upper ends of said posts, a walking-beam pivoted on said rod, means connected with one end of said walking-beam for grasping the drilling-cable, means for actuating said walking-beam, a hand-lever mounted on the foundation-frame, and a connecting-rod extending from said lever to the superstructure that tilts said superstructure rearward away from the well being drilled when such movement is desired.

811,948. **FOLDING UMBRELLA.** JOHN H. NEWEL, Washington, Pa. Filed Nov. 18, 1904. Serial No. 233,468.

Claim.—In a folding umbrella, the combination of a sectional handle adapted to be screwed together, of sectional bows or ribs secured to said handle and provided with a single hinge-joint, together with an annular slide or clasp for embracing the joint and preventing the bows or ribs from folding when the umbrella is in use, all substantially as and for the purposes shown and described.

811,948.



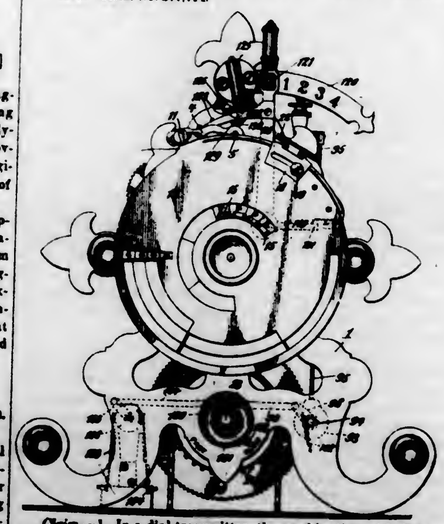
811,949. **STAMP.** HENRY H. NORRINGTON, West Bay City, Mich. Filed July 11, 1904. Serial No. 216,161.

Claim.—1. In combination with a stamp of the class described; a fixed bracket-plate connecting the two side members of said stamp; a plate pivotally mounted on said bracket-plate near its middle; said plate being adapted to revolve in its own plane and parallel to the plane of said bracket-plate; and stamps on the opposite edges of said revoluble plate.

2. In combination with a stamp of the class described, a bracket-plate immovably secured to said stamp; a plate pivotally mounted near its middle on said bracket-plate, said plate being adapted to revolve in its own plane about said pivot and having its opposite edges turned up; and stamps secured to said turned-up edges.

3. In combination with a stamp of the class described, a bracket-plate immovably secured to said stamp; a plate pivotally mounted near its middle on said bracket-plate, said plate being adapted to revolve in its own plane about said pivot and having its opposite edges turned up; and stamps secured to said turned-up edges; together with outwardly-projecting flanges on the ends of said plate, for the purposes set forth.

811,950. **DIAL-TRANSMITTER.** CHARLES F. PEARCE, New York, N. Y., assignor to Frederick Pearce, New York, N. Y. Filed Sept. 9, 1905. Serial No. 277,714.



Claim.—1. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the

other, of a retarding device for regulating the speed of such rotation, said retarding device including two fly-fans mounted upon one spindle and arranged normally to rotate together, and means for disconnecting one of said fans from rotative relation with the other said fan.

2. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of a retarding device for regulating the speed of such rotation, said retarding device comprising two fly-fans arranged to rotate synchronously, and means for disconnecting one of said fans, and for holding it positively against rotation at such times, while the other fan is permitted to rotate freely.

3. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of a retarding device for regulating the speed of such rotation, said retarding device comprising a clock-train and two fly-fans arranged to rotate in unison, a circuit-selecting switch, and hand operating means therefor, a cam, also operated by said hand operating means, and means controlled by said cam for disconnecting one of the said fly-fans.

4. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of speed-retarding means for controlling the speed of such rotation, including a gear-train and two fly-fans, said fans comprising a main and a supplemental fan arranged to normally engage each other, means for disengaging the supplemental fan from engagement with the other fan, a circuit-selecting switch, and means for operating the said circuit-selecting switch at the time the said supplemental fly-fan is caused to engage or disengage the other said fan.

5. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of a retarding device for regulating the speed of such rotation, said retarding device comprising two normally connected fly-fans and means for freeing one of said fans from engagement with the other.

6. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of a retarding device for regulating the speed of such rotation, said retarding device comprising a clock-train, a spindle in gear therewith, a fly-fan in driving relation upon said spindle, another fly-fan loosely surrounding said spindle, but provided with a portion adapted to engage a part in driving relation with said spindle, whereby the two said fans may rotate together, and means for lifting said fan out of such driving relation, and for holding said fan entirely clear of said spindle, and parts rotating therewith.

7. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of a retarding device, including a clock-train, a spindle in gear therewith, a fan in driving relation upon said spindle, another fan loosely mounted upon said spindle, said fan provided with a flange, a lever engaging said flange for lifting said fan into and out of driving relation with the first said fan, and a housing for receiving said flange.

8. In a dial-transmitter, the combination with a plurality of dials adapted to be rotarily adjusted, one with respect to the other, of a clamp for simultaneously locking all of the said dials together.

9. In a dial-transmitter, the combination with a plurality of dials adapted to be rotarily adjusted, one with respect to the other, individual locking means between the said dials, and an independent clamp for clamping all of the said dials together in their adjusted positions.

10. In a dial-transmitter, the combination with a plurality of dials adapted to be rotarily adjusted, one with respect to the other, of a clamp for locking the said dials together, comprising a bracket secured to one dial and overhanging the others, a cam arranged in its operation to clamp the dials between itself and the said bracket, and an operating-lever for said cam.

11. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of driving means for effecting such rotation, a clutch for said driving means, clutch-releasing mechanism, tripping means therefor, and an actuating device in which energy is stored during the aforesaid rotation to be imparted to the clutch-releasing mechanism when the same is tripped.

12. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of driving means for effecting such rotation, a clutch for said driving means, clutch-releasing mechanism, tripping means therefor, and a spring-plunger arranged to engage the clutch-releasing mechanism during the aforesaid rotation, and a little prior to the operation of the tripping mechanism.

13. In a dial-transmitter, the combination with dials and a controlling-arm, of driving means for rotating the controlling-arm, a clutch for said driving means, clutch-operating mechanism, tripping means including a locking-detent engaging a part of said clutch-releasing mechanism, a spring-pressed plunger for engaging said clutch-operating mechanism during the movement of the arm, and a projection for operating said tripping means upon a further movement of said arm.

14. In a dial-transmitter, the combination with dials, a controlling-arm, and driving means for rotating the one with respect to the other in one direction, of spring-pressed means for returning the parts to normal position, means for adjusting the tension thereof, and a retarding device for regulating the speed of such return movement.

15. In a dial-transmitter, the combination of a dial, a controlling-arm, and means for rotating the one with respect to the other, the said means comprising a gear-train, and a weight-motor, the weight-motor composed of two chain-wheels, one connected to the gear-train and the other to winding means, an endless chain arranged over said chain-wheels with a loop between them, a weight suspended from said loop, idler-wheels secured to a stationary support around which the other end of the chain is passed, and an idler-pulley upon the said weight for supporting the opposite loop of said chain, substantially as set forth.

16. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of circuit make and break devices operated during the said rotation, and means operated by the relative rotation of said parts for mechanically throwing the circuit make and break devices into and out of operative relation.

17. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of line-circuit make and break devices controlled thereby, and means for throwing the said circuit make and break devices into and out of operative relation, said means including an electromagnet and a local-circuit breaker.

18. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of line-circuit make and break devices controlled thereby, means for mechanically throwing the circuit make and break devices into and out of operative relation, and locking means for holding them in their position in operative relation, when so adjusted.

19. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of line-circuit make and break devices controlled thereby, means electrically controlled for mechanically throwing the circuit make and break devices into and out of operative relation, and eccentrically-controlled locking means for holding them in their position in operative relation when so adjusted.

20. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of cams connected for rotation therewith, contact-springs arranged to be operated by said cams, and means for moving said contact-springs into and out of operative relation with said cams.

21. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of cams connected for rotation therewith, contact-springs arranged to be operated by said cams, and electrically-controlled means for moving said contact-springs into and out of operative relation with said cams.

22. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of cams connected for rotation therewith, contact-springs arranged to be operated by said cams, means for moving said contact-springs into and out of operative relation with said cams, and locking means for holding them in their position in operative relation when so moved.

23. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of cams connected for rotation therewith, contact-springs arranged to be operated by said cams, means for moving said contact-springs into and out of said operative relation with said cams, and electrically-controlled locking means for holding them in their position in operative relation when so moved.

24. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of cams connected for rotation therewith, contact-springs arranged to be operated by said cams, means including an electromagnet for moving said contact-springs into and out of operative relation with said cams, and a local-circuit breaker for said electromagnet.

25. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of

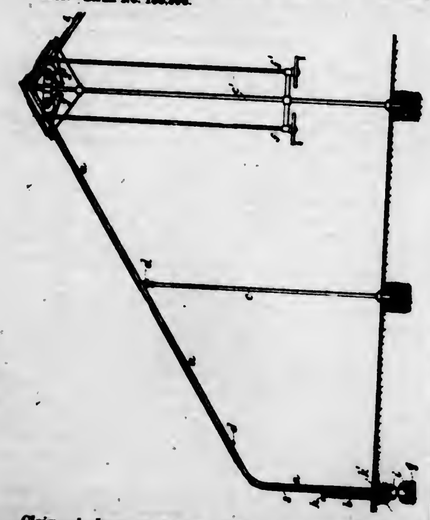
cams connected for rotation therewith, contact-springs arranged to be operated by said cams, means including an electromagnet for moving said contact-springs into and out of operative relation with said cams, and an electromagnet locking and releasing device therefor.

26. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of cams connected for rotation therewith, pivoted contact-springs arranged to be operated by said cams, an electromagnet, an armature therefor connected to said contact-springs, and a local-circuit breaker for said electromagnet.

27. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of cams connected for rotation therewith, pivoted contact-springs arranged to be operated by said cams, an electromagnet, an armature therefor connected to said contact-springs, a latch for holding said armature in its attracted position, and electromagnetic means for releasing said latch.

28. In a dial-transmitter, the combination with dials, a controlling-arm, and means for rotating the one with respect to the other, of cams connected for rotation therewith, pivoted contact-springs arranged to be operated by said cams, an electromagnet, an armature therefor connected to said contact-springs, a latch for holding said armature in its attracted position, electromagnetic means for releasing said latch, and a local circuit make and break device for alternately making and breaking circuit through the said electromagnetic means.

811,951. **GREENHOUSE AND OTHER GLAZED STRUCTURE.** PAUL M. PIERSON, Cushing, N. Y., assignor to The Pierson-Sefton Company, Jersey City, N. J., a Corporation of New Jersey. Filed May 7, 1903. Serial No. 156,006.



Claim.—1. In a greenhouse or similar glazed structure, a series of sash-bars substantially continuous and extending unbroken from the foundation to a point adjacent to the ridge-bar, and each comprising a bent form of metal bar for strength and a part connected thereto and to which the glasses are in turn connected, said bars each including the short vertical side, the inclined top and curved intersection.

2. In a greenhouse or similar glazed structure, a series of sash-bars substantially continuous and extending unbroken from the foundation to a point adjacent to a termination-plate, and each comprising a bent form of metal bar for strength and a part connected thereto and to which the glasses are in turn connected, said bars each including the short vertical side, the inclined top and curved intersection, and with plates of glass contacting at the meeting edges and extending between the sash-bars and continuous for the length of said complete bars.

3. In a greenhouse or similar glazed structure, a series of sash-bars substantially continuous and extending unbroken from the foundation approximately to the center ridge-bar and each comprising a form of metal of bent cross-section for strength, and a wooden bar covering and lying parallel with and connected to the metal bar and constructed to receive the plates or lights of glass, and each of which sash-bars includes the short vertical side, the long inclined top part and curved intersection.

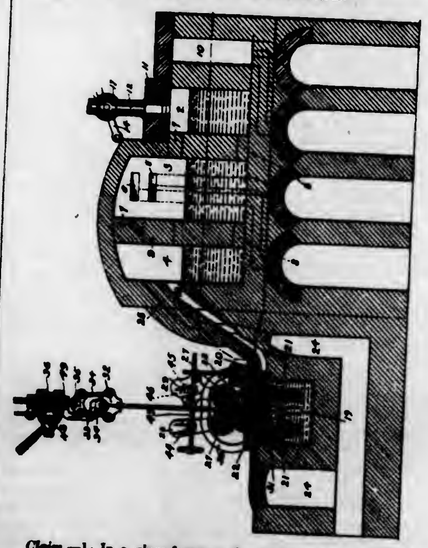
4. In a greenhouse or similar glazed structure, a series of sash-bars substantially continuous extending unbroken from the foundation approximately to the center ridge-bar and each comprising a form of metal of U shape in cross-section for strength, and a wooden bar received in and covering with the metal bar lying parallel with and connected to the metal bar and having a projecting rib of narrower width with side shoulders to receive putty as seats for the plates or lights of glass, and each of which sash-bars includes the short vertical side, the long inclined top part and curved intersection.

5. In a greenhouse or other glazed structure, a series of sash-bars substantially continuous and each comprising the short vertical sides, the inclined top and curved intersection, and each bar consisting of a metal part for strength and a wooden part parallel and continuous, the wooden part at one end stopping at the sill and at the other end at the ventilating-sashes near the top, and the metal bar continuing at the top to a connection with the ridge-bar and at the other and lower end to connection with the foundation.

6. In a greenhouse or similar glazed structure, a series of sash-bars each comprising a short vertical side, an inclined top and curved intersection, and composed at the curved intersection and adjacent portions of an inner or under part of metal and an outer part of wood.

7. In a greenhouse or similar glazed structure, a series of sash-bars substantially continuous and extending from the foundation to a point adjacent to the ridge-bar and each comprising a bent form of metal for strength and a part connected thereto and to which the glasses are in turn connected, said bars each including the short vertical side, the inclined top and curved intersection, and plates of glass between the sash-bars from end to end forming a continuous surface of glass.

811,952. **GLASS-TANK FURNACE.** JULIUS PROBERT, Greensburg, Pa. Filed Jan. 26, 1904. Serial No. 190,949.



Claim.—1. In a glass-furnace, the combination of a melting-chamber or source of supply of molten glass, a delivery-chamber for delivering the molten glass for further treatment, and fluid-pressure devices for driving the glass from the melting-chamber to the delivery-chamber by the direct action of the fluid-pressure upon the molten glass; substantially as specified.

2. In a glass-furnace, the combination of a melting-chamber, a fluid-pressure chamber, a refining or delivery chamber, said chambers having communicating passages one with the other, a drawing-chamber, and a communicating passage between the refining-chamber and the drawing-chamber; substantially as specified.

3. In a glass-furnace, the combination of a source of supply of molten glass, a drawing or gathering tank situate on a level below the level of the source of supply, a passage leading to the drawing or gathering tank, from the source of supply, at a point above the normal level of the glass in said source of supply, and fluid-pressure devices for causing the molten glass to rise to the level of the passage leading from the source of supply to the gathering-tank and to flow through such passage; substantially as specified.

4. In a glass-furnace, the combination of a melting-chamber, a refining or delivery chamber, a fluid-pressure chamber having fluid-pressure devices, said chambers having open passages one from the other, a drawing or gathering tank, a passage leading from the source of supply of molten glass to the gathering or drawing tank, and heating-flues arranged in the walls of said furnace, whereby the gathering or drawing tank and the passage leading thereto may be kept at a temperature sufficient to prevent the congealing of the molten glass in the tank; substantially as specified.

5. In a glass-furnace, the combination of a source of supply of molten glass, fluid-pressure devices for driving the glass from the source of supply, a gathering or drawing tank, a passage connecting the source of supply and the gathering or drawing tank, and a movable gate for closing the connection between said passage and the drawing or gathering chamber; substantially as specified.

6. In a glass-furnace, the combination of a source of supply of molten glass, a drawing-tank, a passage connecting the source of supply with the drawing-tank, a gate for opening and closing said passage, a wing, or wings, situate in said drawing-tank and dividing the tank into compartments, said compartments communicating with each other below the normal surface of the glass, a fluid-pressure passage leading into one of said compartments, and a slot situate in the cover of another of said compartments; substantially as specified.

7. In a glass-furnace, the combination of a melting-tank, a fluid-pressure chamber, devices for applying fluid-pressure to the molten glass, said chambers communicating one with the other, a delivery-passage for the delivery of the molten glass, and a receptacle situate below said passage; substantially as specified.

8. In a glass-furnace, the combination of a melting-chamber, a gathering-tank, a fluid-pressure chamber at one end of the gathering-tank, and a delivery-chamber at the other end of the gathering-tank, said chambers and tanks communicating with each other, and fluid-pressure devices for causing the circulation of the molten glass through said chambers; substantially as specified.

811,953. **NECK-YOKE CENTER.** HENRY B. GUNN, Comstock, Tex., assignor of one-half to Alfred A. Newell, Comstock, Tex. Filed Mar. 3, 1905. Serial No. 248,208.

Claim.—1. A neck-yoke center comprising a tubular member, an inclined collar thereon, a protecting-piece surrounding the tubular member and resting against the collar, a washer varying in thickness and surrounding the tubular member, said washer abutting against the protecting-piece, and a collar movably engaging the tubular member and bearing against the washer.

2. A neck-yoke center comprising a tubular member having an inclined collar thereon, the rear end of the tubular member extending beyond the inclined collar, a pointed projection upon the inclined collar, a protecting-piece having a squared upper end, said protecting-piece surrounding the tubular member and resting against the inclined collar and pointed projection, an irregular washer having a thickened and beveled upper portion, said washer surrounding the tubular member and resting against the protecting-piece, a removable squared and beveled collar screwed upon the tubular member and holding the irregular washer in position, and a screw extending between the removable collar and the tubular member for locking said collar in position.

811,954. **METHOD OF BRAZING STEEL AND COPPER.** JOHN F. RICHARDSON, Pittsburg, Pa. Filed Oct. 27, 1904. Serial No. 230,586.

[redacted]

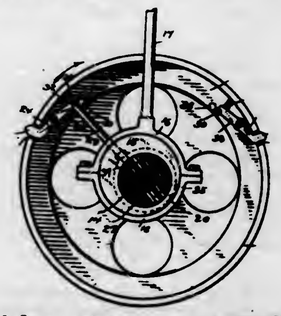
Claim.—1. A method of brazing steel and copper, consisting of heating a piece of steel to a white heat, then spreading a flux over the surface of the steel, the placing a thin sheet of brass substantially coextensive with the steel thereon and again spreading a suitable flux upon the surface of the brass and then laying the piece of copper which is to be welded to the steel upon the flux and brass, and then submitting the same to suitable rolls or a compressor whereby the three sheets of material are compressed, substantially as described.

2. A method of brazing steel and copper, consisting of heating a piece of steel to a white heat and spreading a flux upon its one surface, then applying a thin sheet of brass of an area equal to that of said surface to this surface and again spreading a flux upon the brass, and then placing a piece of copper to be brazed to the steel upon the sheet of brass and flux and submitting the same to a compressing means whereby they are forced into engagement with each other under pressure.

3. The method of forming a composite sheet of steel and copper consisting in heating a sheet of steel, applying a flux to said sheet while the sheet is in heated condition, then laying a sheet of brass upon the sheet of steel, then laying a sheet of copper upon said sheet of brass and melting the sheet of brass by the initial heat of said sheet of steel, and then while the brass is in melted condition compressing the composite sheet.

4. The method of brazing steel and copper consisting of heating the steel, placing a flux upon said steel, then placing brass upon said steel, and lastly placing a sheet of copper upon said brass, and then welding said metals together by pressure while the steel retains a part of its initial heat.

811,955. **REVERSING MECHANISM FOR EXPLOSIVE-ENGINES.** EDWIN B. ROBERTSON, East Norwalk, Conn. Filed Feb. 20, 1905. Serial No. 246,408.



Claim.—1. In an explosive-engine, the combination with a shaft, a fly-wheel and spring-controlled oppositely-acting driving-dogs and corresponding stop-pins on its inner face, of an eccentric having a loosely-mounted hub, an ignition device operated by the eccentric, and a rod extending from the eccentric-hub into the path of the driving-dogs and stop-pins, substantially as described, for the purpose specified.

2. In an explosive-engine, the combination with a fly-wheel having a hub provided with a circumferential groove and spring-controlled oppositely-acting driving-dogs and corresponding stop-pins on its inner face, of an eccentric having a hub loose on the fly-wheel hub, an ignition device operated by the eccentric, a rod carried by the eccentric-hub and extending into the path of the driving-dogs and stop-pins, and a pin engaging the groove in the fly-wheel hub, substantially as described, for the purpose specified.

3. In an explosive-engine, the combination with a fly-wheel having openings in its periphery and spring-controlled oppositely-acting driving-dogs and corresponding stop-pins on its inner face, said driving-dogs having arms projecting through the openings in the periphery of the fly-wheel, of an eccentric having a loosely-mounted hub, an ignition device operated by the eccentric, and a rod extending therefrom into the path of the driving-dogs and stop-pins, the eccentric being operated by one of said driving-dogs when the fly-wheel is turning forward and by the other driving-dog when it is reversing.

4. The combination with an explosive-engine having a body provided with a hub, and a fly-wheel provided with a hub and having oppositely-acting driving-dogs and corresponding stop-pins on its inner face, of an eccentric having a hub loosely mounted on said body and fly-wheel hubs, and having a rod extending into the path of the driving-dogs and stop-pins, and an ignition device operated by the eccentric.

5. The combination with the body of an explosive-engine having a hub, and a fly-wheel provided with a hub having a circumferential groove, and oppositely-acting driving-dogs and corresponding stop-pins on its inner face of an eccentric having a hub loosely mounted on said body and fly-wheel hubs and having a rod extending into the path of the driving-dogs and stop-pins and a pin engaging the groove in the fly-wheel hub, whereby the eccentric-carrying hub is held against lateral displacement and an ignition device operated by the eccentric.

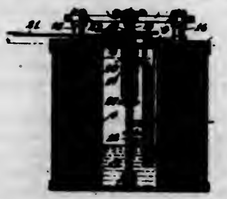
6. In an explosive-engine, the combination with a fly-wheel having a hub and oppositely-acting driving-dogs and corresponding stop-pins on its inner face of an eccentric having a hub with a rod extending into the path of the driving-dogs and stop-pins, said rod being locked between one driving-dog and the corresponding stop-pin to actuate the eccentric when the fly-wheel is turning forward and being locked between the other driving-dog and the corresponding stop-pin to actuate the eccentric when the fly-wheel is reversing and an ignition device operated by the eccentric.

7. In an explosive-engine, the combination with a fly-wheel having openings in its periphery, and spring-controlled oppositely-acting driving-dogs and corresponding stop-pins on its inner face, said driving-dogs having arms projecting through the openings in the fly-wheel in position to be tripped and notches at their inner ends of an eccentric having a hub with a rod extending therefrom, the outer end of said rod being adapted to be locked between one of the driving-dogs and the corresponding stop-pin and driven by said dog to actuate the eccentric when the fly-wheel is turning forward and to be engaged by the other stop-pin to again pick up the eccentric after the forward driving-dog has been tripped and to be locked between the stop-pin by which it has been engaged and the other driving-dog and be driven by the latter to actuate the eccentric when the fly-wheel is reversing and an ignition device operated by the eccentric.

8. In an explosive-engine, the combination with a fly-wheel having spring-controlled oppositely-acting driving-dogs and corresponding stop-pins on its inner face of an eccentric having a loosely-mounted hub with an arm extending into the path of the driving-dogs and stop-pins and an ignition device operated by the eccentric, substantially as described, for the purpose specified.

9. In an explosive-engine, the combination with a fly-wheel having spring-controlled oppositely-acting driving-dogs and corresponding stop-pins on its inner face of an eccentric having a loosely-mounted hub with a rod extending into the path of the driving-dogs and stop-pins, means for retaining the eccentric-hub against lateral movement and an ignition device operated by the eccentric.

811,956. **ELECTRICAL MEASURING INSTRUMENT.** MAURICE C. RYPINSKI, New York, N. Y. Filed Mar. 15, 1905. Serial No. 250,189.



Claim.—1. In an electrical measuring instrument the combination of a stationary coil, a receptacle containing a damping fluid supported within said coil, a moving system comprising magnetic members suspended within said receptacle, and an indicating-needle supported exteriorly of the receptacle.

2. In an electrical measuring instrument the combination of a stationary coil, a removable receptacle containing a damping fluid supported within said coil, and a moving piston supported within said receptacle.

3. In an electrical measuring instrument the combination of a stationary coil, a removable receptacle containing a damping fluid supported within said coil, a moving system supported within said receptacle, and means to prevent the escape of said fluid from said receptacle in whatever position the instrument may be placed.

4. In an electrical measuring instrument the combination of a stationary coil, a receptacle containing a damping fluid supported within said coil, an apertured cap closing one end of said receptacle, a moving system comprising a shaft passing through the cap-aperture and supported on a bearing in said receptacle, and means to prevent the escape of the damping fluid through said aperture.

5. In an electrical measuring instrument the combination of a stationary coil, a removable receptacle containing a damping fluid supported within said coil, a moving system supported within said receptacle, said system comprising a pivoted shaft having a magnetic member attached thereto.

6. In an electrical measuring instrument the combination of a stationary coil, a receptacle containing a damping fluid supported within said coil, an apertured cap closing one end of said receptacle, a moving system comprising a shaft passing through the cap-aperture, and a fluid-deflector secured to said shaft.

7. In an electrical measuring instrument the combination of a stationary coil, a removable receptacle containing a damping fluid supported within said coil, a moving system comprising a shaft, bearings for said shaft one of which is within said receptacle and the other carried by a frame supported on said receptacle.

8. In an electrical measuring instrument the combination of a stationary coil, a removable receptacle containing a damping fluid supported within said coil, a moving system supported within said receptacle, said system comprising a shaft having secured thereto a magnetic member and an indicating-needle, and a scale-plate secured to said receptacle.

9. In an electrical measuring instrument the combination of a stationary coil, a removable receptacle containing a damping fluid supported within said coil, a cap closing one end of said receptacle, a fixed magnetic member secured to said cap, and a moving magnetic member suspended in said receptacle and normally adjacent to said fixed member.

811,957. **LOCK-NUT.** CHARLES RYSTROM, Rockford, Ill. Filed Mar. 13, 1906. Serial No. 147,992.

Claim.—1. As a new article of manufacture, a lock-nut composed of a spirally-coiled body having flattened outer faces an internal screw-threaded opening, the coils in their normal position being separated, and means carried by the nut for holding the coils compressed.

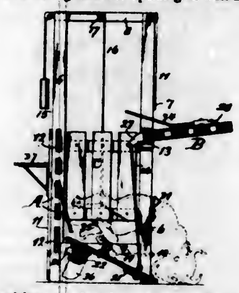
2. As a new article of manufacture, a lock-nut composed of a spirally-coiled body having an internal screw-threaded opening the coils of which normally tend to separate and in which position they are out of register, and removable clips carried by opposite sides of the nut normally tending to hold the coils compressed and the threads in continuous register.

3. As a new article of manufacture, a resilient, spirally-coiled body having an internal screw-threaded opening and having external flattened portions, and a plurality of removable clips holding said coiled body in a compressed condition, each of said clips being flattened on its outer side and bearing internally against one of the flattened portions of said coiled body.

4. As a new article of manufacture, a lock-nut comprising a compressible and expansible spirally-coiled body having an internal screw-threaded opening, the threads of which are continuous when the coils are compressed and broken when the coils are expanded, said nut being adapted for application to a bolt only when the coils are compressed, and means forming a part of the article and engaging the ends thereof for holding the coils of the nut compressed and the threads continuous so that the nut may be applied to a bolt, said means being removable to permit the coils of the nut to expand.

811,958. **KNOCKING-PEN.** GUSTAV SCHMIDT and FREDERICK SCHMIDGALL, Cincinnati, Ohio, assignors to The Cincinnati Butchers Supply Company, a Corporation of Ohio. Filed July 1, 1905. Serial No. 267,992.

Claim.—1. A knocking-pen forming substantially an inclosure provided with an inlet and an outlet opening, a door to control the inlet, a swinging flap and a tilting floor which control the outlet, locking means to positively hold one of these two latter parts in normal position and means whereby these parts are permanently connected so as to move together for opening as well as for closing.



2. A knocking-pen forming substantially a four-sided box-frame of which one of the ends and a side are movable to permit opening, a floor supported to tilt sidewise, locking devices to hold the movable side in closed position and means to connect this side to the floor to also hold this latter in its normal position and to cause both to move together when the side is unlocked.

3. A knocking-pen forming substantially a four-sided structure of which one of the ends and a side are movable to permit opening, a hingedly-connected floor adapted to tilt transversely, locking-latches to hold the movable side in closed position, operating devices to manipulate them and means to connect this side to the floor to hold this latter in its normal position and to cause also both to move together when the side is unlocked.

4. A knocking-pen forming substantially a four-sided box-frame of which one of the ends and a side are movable to permit opening, a floor supported to tilt, locking-latches to hold the movable side in its closed position, one at each of its ends, mechanism whereby these latches are connected for simultaneous operation and means to connect the movable side to the floor to cause them to move together.

5. In a knocking-pen forming substantially a four-sided box-frame of which one of the ends and a side are movable to permit opening, a floor supported to tilt transversely, locking means to hold the movable side releasably in its closed position, lever-arms projecting from the movable side and links connecting these arms to the floor so that both this latter and the particular side move together.

6. A knocking-pen forming substantially a four-sided box-frame of which one of the ends and a side are movable to permit opening, a floor pivotally supported at its ends and adapted to tilt sidewise, means to manipulate the movable parts and to hold them in normal positions and a leg below this floor to support the same between its ends in normal position.

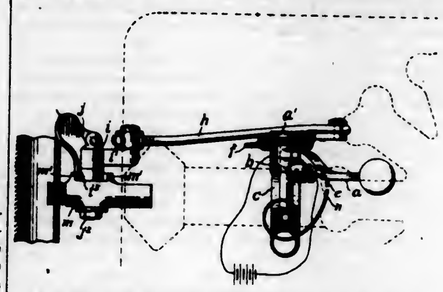
7. A knocking-pen forming substantially a four-sided box-frame, having a movable end to permit entrance, a side supported to swing laterally to permit exit, a bottom adapted to tilt sidewise means to manipulate these parts and a bouncing-board on the inner side of the side opposite the swinging side.

8. A knocking-pen forming substantially a four-sided box-frame of which one of the ends and a side are movable to permit opening, a floor supported to tilt sidewise, means to operate these parts, a platform-stage on the outside of the permanent side and a ladder to mount the same.

811,959. **AUTOMATIC CONTROLLING DEVICE FOR GAS-STOVES.** WILLIAM B. SCHOFIELD and MILLARD P. OSBORN, Merchantville, N. J. Filed Feb. 27, 1905. Serial No. 247,868.

Claim.—1. In an automatic controlling device for gas-stoves and the like, the combination of a bracket having a clamping device for detachable attachment to the stove, a movable primary actuating device carried by said bracket and adapted to be actuated by the weight of a vessel placed upon it, a valve to control the fuel-supply to the burner, power-transmitting connections between said valve and movable primary actuating device, and igniting devices carried by said bracket and controlled by the movement of said primary actuating device.

2. In an automatic controlling device for gas-stoves and the like, the combination of a movable primary actuating device adapted to be moved by a vessel placed on the stove, valve mechanism to control the fuel-supply to the burner, power-transmitting connections between said valve mechanism and the primary actuating part arranged to fully open the supply to the burner through said valve mechanism, and means manually controlled at will to adjust the supply-opening through said valve mechanism and automatically controlled to return said valve mechanism to full position when the valve passage-way is closed by said power-transmitting connections with the primary actuating part, whereby said valve mechanism, when again operated by the placing of a vessel on the stove, will be fully opened irrespective of the previous adjustment of said means controlled at will.



3. In an automatic controlling device for gas-stoves and the like, the combination of a movable primary actuating device adapted to be moved by a vessel placed on the stove, a main valve to control the fuel-supply to the burner, power-transmitting connections between said main valve and primary actuating part, an auxiliary controlling-valve for independently controlling the fuel-supply when said main valve is opened, and means for automatically returning said auxiliary controlling-valve to full position when the main valve is closed.

4. In an automatic controlling device for gas-stoves and the like, the combination of a movable primary actuating device adapted to be moved by a vessel placed on the stove, a main valve to control the fuel-supply to the burner actuated by said primary actuating device to fully open or close the valve passage-way, and an auxiliary hand-controlled controlling-valve carried by said main valve and adapted to control its valve passage-way.

5. In an automatic controlling device for gas-stoves and the like, the combination of a primary actuating device adapted to be moved by a vessel placed on the stove, a main valve to control the fuel supply to the burner actuated by said primary actuating device, and an auxiliary controlling-valve carried by said main valve and moving with it, but independently movable with reference to said main valve to control the valve passage-way thereof.

6. In an automatic controlling device for gas-stoves and the like, the combination of a primary actuating device adapted to be moved by a vessel placed on the stove, a main valve to control the fuel-supply to the burner actuated by said primary actuating device, and an auxiliary controlling-valve carried by said main valve and moving with it, but independently movable with reference to said main valve to control the valve passage-way thereof, and means for returning said auxiliary controlling-valve to normal full position with reference to said main valve when the main valve is actuated.

7. In an automatic controlling device for gas-stoves and the like, the combination of a primary actuating device adapted to be moved by a vessel placed on the stove, a tabular valve *i* located in the fuel-supply pipe and having a port to control the fuel-supply said valve *i* being actuated by the primary actuating device, and an auxiliary independently-adjustable controlling-valve *j* carried by said tubular valve *i* and having a port normally registering with the port of said valve *i*.

8. In an automatic controlling device for gas-stoves and the like, the combination of a primary actuating device adapted to be moved by a vessel placed on the stove, a tabular valve *i* located in the fuel-supply pipe and having a port to control the fuel-supply said valve *i* being actuated by the primary actuating device, and an auxiliary independently-adjustable controlling-valve *j* carried by said tubular valve *i* and having a port normally registering with the port of said valve *i*, and means to move said controlling-valve with its port in register with the port of the valve *i* when the latter is moved into open or closed position by the primary actuating device.

9. In an automatic controlling device for gas-stoves and the like, the combination of a primary actuating device adapted to be moved by a vessel placed on the stove, a rotary tubular valve *i* located in the fuel-supply pipe and having a port to control the fuel-supply, said valve *i* being actuated by the primary actuating device, stops to limit

the movement of said valve *i* at open and closed positions, an auxiliary independently-adjustable controlling-valve *j* carried by said tubular valve *i* and having a port normally registering with the port of said valve *i*, and a projection *b* carried by said valve *j* and adapted to strike the limit-stops of the valve *i* whereby said auxiliary controlling-valve will be automatically returned to position with its port registering with the port of the valve *i* when said valve is moved into open or closed position by the primary actuating device.

10. In an automatic controlling device for gas-stoves and the like, the combination of a primary actuating device adapted to be moved by a vessel placed on the stove, a valve to control the fuel-supply to the burner actuated by said primary actuating device, and an igniting device arranged adjacent to the burner and controlled by the primary actuating device, said igniting device embracing a thermostatic electric sparking point adapted to move out of sparking proximity when heated by the flame from the burner.

11. In an automatic controlling device for gas-stoves and the like, the combination of a primary actuating device adapted to be moved by a vessel placed on the stove, a valve to control the fuel-supply to the burner actuated by said primary actuating device, a pair of sparking points arranged adjacent to the burner and embraced in a normally open electric circuit, a contact-piece in circuit with the source of electric energy and one of said points and a contact-piece carried by the primary actuating device in circuit with the other sparking point.

12. In an automatic controlling device for gas-stoves and the like, the combination of a primary actuating device adapted to be moved by a vessel placed on the stove, a valve to control the fuel-supply to the burner actuated by said primary actuating device, a pair of sparking points arranged adjacent to the burner and embraced in a normally open electric circuit, a contact-piece in circuit with the source of electric energy and one of said points and a contact-piece carried by the primary actuating device in circuit with the other sparking point one of said sparking points consisting of a thermostatic strip adapted to move out of sparking proximity when heated by the flame from the burner.

811,960. **MOUNTING FOR EYEGLASSES.** HARRY A. SEIDEL, Lebanon, Pa. Filed Oct. 27, 1905. Serial No. 284,730.

Claim.—1. An eyeglass-mounting comprising a bridge or spring having guards formed integral therewith on the ends thereof, said guards having an opening therein and provided with laterally-extending flanges, and lugs on the free ends of the guards for attaching posts thereto.

2. An eyeglass-mounting comprising a bridge or spring having guards formed integral therewith on the ends thereof, said guards having an opening therein and provided with inwardly-extending flanges, and protuberances, and lugs for attaching posts thereto.

3. An eyeglass-mounting comprising a rod-like bridge or spring having integral guards at the ends thereof provided with an opening, and laterally-extending flanges bounding part of the opening, and lugs for attaching posts thereto.

4. An eyeglass-mounting comprising a bridge or spring having bends at the ends thereof and terminating in open guards integral therewith and having inwardly-extending flanges, and lugs at the ends of the guards.

5. An eyeglass-mounting comprising a bridge or spring having a bend at each end, a bend adjacent the first bend, guards integral with the bridge at the ends thereof, approximately C-shaped, and provided with laterally-extending flanges, and lugs.

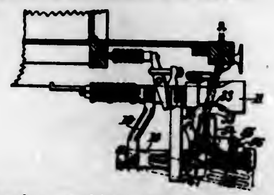
811,961. **AUTOMATIC AIR-COUPLING.** EDMUND V. SHIRTZ, Fond du Lac, Wis., and DENVER B. MOURNER, Belle Plaine, Iowa. Filed Apr. 12, 1905. Serial No. 255,262.

Claim.—1. An air-coupler having a horizontally-slidable block for connecting it with the draw-bar of a car, said block being adapted to yield to conform to the horizontal play of the draw-bar.

2. An air-coupler having a sliding block, said block being provided with a transverse pin for pivotally connecting it with the draw-bar of a car.

3. An air-coupler comprising a supporting member having a slidable block for connecting it with a draw-bar, and a coupling member movably connected with the supporting member.

4. An air-coupler comprising a supporting member having a slidable block for connecting it with a draw-bar, a coupling member movably connected with the supporting member, and resilient means for normally holding said members in alinement.



5. A coupler, comprising two members, one member having a depression and the other member having a longitudinal spring entering said depression to yieldingly retain the members in alinement.

6. An air-coupler comprising a supporting member, and a coupling member having a spring projecting toward the supporting member, the supporting member having means for engaging the spring, said spring normally acting to keep said members in alinement.

7. An air-coupler comprising a supporting member, and a coupling member having a longitudinal bar-spring projecting toward the supporting member, the supporting member having means for engaging the spring; said coupling member having an air-brake passage therein, a valve in the passage, and a stem for the valve adapted to be operated by a companion coupler.

8. An air-coupler comprising a coupling member having an air-brake passage, a valve movable longitudinally of the coupler and adapted to close the passage, a longitudinal stem projecting beyond the surface of said member, and a rearwardly-inclined surface adapted to engage a similar projecting stem of a companion coupler.

9. An air-coupler comprising a coupling member having a projection provided with a slanting lower surface and with a notch, and a plate adjacent to said projection corresponding in shape with the notch but extending in the opposite direction.

10. An air-coupler comprising a coupling member having a pair of projections, one of said projections being provided with a slanting lower surface and adapted to enter a space between similar projections upon the companion coupling member, a notch on one of said projections, and a plate corresponding in shape with the notch but extending in the opposite direction.

11. An automatic air-coupler comprising a coupling member having a pair of projections, one of said projections being provided with a slanting lower surface and adapted to enter a space between similar projections upon a companion coupling member, the projection having a slanting surface, being provided with a notch, and the coupling member being provided with a plate between the two projections, said plate corresponding in shape with the notch but extending in the opposite direction.

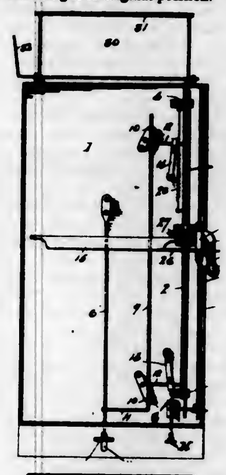
12. An automatic air-coupler comprising a coupling member having means for locking it to a companion member of the same shape, said coupling member being provided with a passage for the air of an air-brake system, a passage for connection with an air-signal system, and a steam-passage, each of said passages having an outlet and said outlets being located adjacent to each other upon the inner surface of the coupling member.

811,962. **COPY-HOLDER.** CHARLES V. SHANNON, Dawson, Canada. Filed June 23, 1904. Serial No. 213,377.

Claim.—1. In a copy-holder, the stationary rack-bar and carriage connected thereto, a movable rack-bar having slots therein, a rock-bar having lifting-bars located in said slots, and a depressible spring-rod for rocking said rock-bar to lift the movable bar, whereby the carriage is disengaged from the stationary rack-bar and engaged by the movable rack-bar.

2. In a copy-holder and spacer, a stationary rack-bar and carriage connected thereto, a space-bar on said carriage, a movable rack-bar having slots therein, a rock-bar having lifting-rods located in said slots, a depressible rod bearing on said rock-bar adapted to lift the movable bar whereby the carriage is disengaged from the stationary rack-bar and engaged by the movable rack-bar, and means for returning the movable rack-bar to normal position when pressure is released on the depressible bar, all combined substantially as described.

3. The combination of a stationary rack-bar and a slotted movable rack-bar, a carriage and a series of pawls carried thereby engaging said stationary bar, a space-bar carried by the carriage, a rock-bar having rocker-arms in the slots of the movable bar for lifting said bar whereby the pawls are disengaged from the stationary bar and engaged by the movable bar, and a spring connected to the movable bar for returning it to original position.



811,963. **TARGET.** HERBERT A. SHAULIS, New York, N. Y., assignor to Shaulis Amusement Construction Company, New York, N. Y., a Corporation of New York. Filed July 3, 1905. Serial No. 268,146.

Claim.—1. A game apparatus comprising a figure of a base-ball batter and of a base-ball catcher, with means for supporting them in upstanding positions; the figure of the batter being provided with an extended bat, and also with means for signaling when the bat is struck by a ball thrown by the player.

2. A game apparatus comprising a figure of a base-ball batter and a figure of a catcher, with means for supporting them in upstanding positions; the figure of the batter being provided with an extended bat, and the figure of the catcher being provided with a receptacle into which may drop some of the balls thrown past the bat.

3. A game apparatus comprising a figure of a base-ball batter and a figure of a catcher, with means for securing and bracing each of them in upstanding position; the figure of the batter being provided with an extended bat, which is movably mounted upon said batter, so as to be displaceable by a ball striking the same while the batter remains motionless.

4. A game apparatus comprising a figure of a base-ball batter and a figure of a catcher, with means for securing them in upstanding position; the figure of the batter being provided with an extended bat, which is movably mounted so as to be displaceable by a ball striking the same while the batter remains motionless, and means for returning said bat to normal position after being struck.

5. A game-set comprising a profiled figure of a base-ball batter and a profiled figure of a catcher, with means for securing them in upstanding positions; the figure of the batter being provided with an extended bat, and each of said figures being formed of a plate of metal suitably painted upon its front side, with a stiffening-rib, such as 7, fixed upon the back of each plate.

6. A game apparatus comprising a profiled figure of a base-ball batter and a profiled figure of a catcher, the figure of the batter being provided with an extended bat, each of said figures provided with prongs upon its feet to stick into the ground or floor, and also with a hinged rear support or brace to rest upon the ground.

7. A game apparatus comprising a figure of a base-ball batter and a figure of a catcher, with means for supporting them in upstanding positions; the figure of the batter being provided with an extended bat and with means for signaling whenever the bat is struck by a ball thrown by the player, and the figure of the catcher being provided with a receptacle into which may drop some of the balls thrown past the bat.

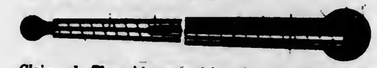
8. A game apparatus comprising a figure of a base-ball batter and a figure of a catcher, both having means whereby they may be secured and braced upon the ground or floor; the figure of the batter being provided with an extended bat and with means for signaling whenever the bat is struck by a ball thrown by the player, and an opening being formed in the body of the catcher, and a receptacle being provided in rear of said opening for the balls thrown at the bat.

9. A game apparatus comprising a figure of a base-ball batter and a profiled figure of a base-ball catcher; the batter being provided with an extended bat, and the catcher having a receptacle for the thrown balls, the opening for said receptacle being in the body of the catcher.

10. A game apparatus comprising a figure of a base-ball batter provided with an extended bat, which is hinged upon the body of the batter, and a figure of a catcher, provided with a receptacle for balls thrown at the bat.

11. A game apparatus comprising a profiled figure of a base-ball batter and a profiled figure of a catcher, each of said figures provided with prongs upon its feet to stick into the ground or floor, and also with a hinged rear support or brace to rest upon the ground, the figure of the batter being provided with an extended bat and with means for signaling when the bat is struck, and the figure of the catcher having a receptacle for the thrown balls.

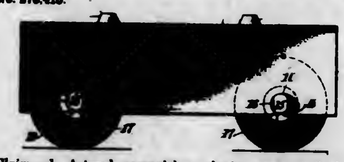
811,964. **TOY WHIP.** WILLIAM F. SIMON, West Hoboken, N. J. Filed Aug. 22, 1904. Serial No. 221,698.



Claim.—1. The whip comprising the core, the exterior body formed of thin narrow coiled metal, the interior string fastened at the outer end of said body to prevent undue extension of the same, and the knob fastened on the butt-end of said core, said knob having a cavity to receive the said end of said core and the adjacent ends of said body and string; substantially as set forth.

2. The whip comprising the core, the exterior body formed of thin narrow coiled metal, the interior string, and the knobs at the ends of said body, said string being fastened at its inner end at the base of said core and at its outer end connected with the outer one of said knobs; substantially as set forth.

811,965. **TRUCK.** JOHN D. SMYTH, Cheraw, S. C., assignor of one-half to Pee Dee Iron Works, Cheraw, S. C. Filed Aug. 23, 1905. Serial No. 275,410.

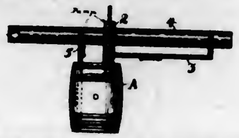


Claim.—1. A truck comprising a body constructed of a single piece of material bent upon itself to form an upper section and downwardly-extending side sections, the side sections being provided with transversely-alined openings, an axle provided with grooves for receiving the side walls of the openings, and wheels loosely mounted on the axle within the said body.

2. In a truck, a body constructed of one piece of sheet metal, comprising an upper section having guides for the articles carried, and downwardly extending side members provided with openings in their lower edges, the said openings being in transverse alinement, and axles introduced into the said openings, which axles have grooves in their sides receiving the side walls of the said openings, and wheels mounted loosely on the said axles within the said body.

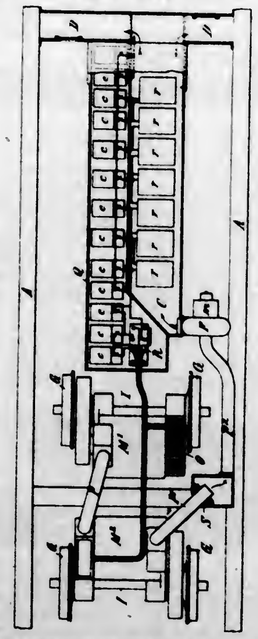
3. In a truck, the combination with a body constructed of one piece of metal bent upon itself to form a top section having a guide for the material to be carried, and downwardly-extending side sections having vertical slots in their lower edges adjacent to the ends of the sides, transversely-opposing slots being in transverse alinement, axles provided with grooves in opposite sides at their ends, which grooves are adapted to receive the side walls of the openings in the body, the lower edges of the side walls of the said openings being projected beneath the said axles, and wheels loosely mounted on the said axles within the body, the washers of said wheels extending practically to the side members of the body, as set forth.

811,966. **MEANS FOR AGING AND PURIFYING LIQUORS.** ROBERT A. STEWART, San Francisco, Cal., assignor of one-half to A. J. Knoblock, San Francisco, Cal. Filed Feb. 3, 1904. Renewed Dec. 11, 1905. Serial No. 291,265.



Claim.—An apparatus for aging and purifying alcoholic liquors consisting of a containing vessel, a chamber 4 supported in rotation with the vessel and having a pipe extending into the vessel to a point near the bottom thereof, a pump connected to the upper part of the vessel, a pipe 3 connected to the pump and to the chamber, and a valve in the chamber for the admission of fresh accretions of oxygen thereto.

811,967. **ELECTRIC CAR.** LEWIS B. STILLWELL, Lakewood, N. J. Filed July 29, 1904. Serial No. 218,695.



Claim.—1. In electric cars the combination of a motor and rheostats, chambers containing said elements, means for causing a current of air at substantially atmospheric pressure to flow through said chambers and for conveying the air so heated to the interior of the car.

2. In electric cars the combination of a chamber beneath the floor of the car, a heat-generating element of the electrical motive-power equipment of said car contained in said chamber, a fan, or equivalent device, for causing a current of air at substantially atmospheric pressure to flow through said chamber, and a conduit connecting said chamber with the interior of said car.

3. In electric cars the combination of a chamber, a heat-generating element of the electrical motive-power equipment of said car contained in said chamber, a fan rotated by the motor propelling said car, means for automatically maintaining the direction of the moving air into or out of the car constant irrespective of the direction in which the motor rotates, and a conduit connecting said chamber with the interior of said car.

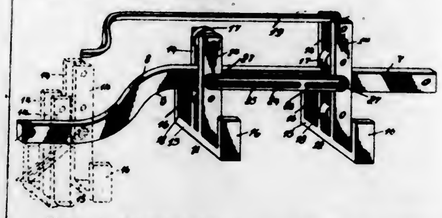
4. In electric cars the combination of a chamber, a heat-generating element of the electrical motive-power equipment of said car contained in said chamber, an entrance-passage to said chamber provided with a valve, means for automatically shifting said valve as the direction of the movement of the car is reversed, and means for conveying the air thus heated to the interior of the car.

5. In electric cars, the combination of a chamber, a heat-generating element of the electric motive-power equipment of said car contained in said chamber, an entrance-passage to said chamber provided with a valve and means for shifting said valve as the direction of the movement of the car is reversed, said means consisting of electrically-actuated mechanism interlocked with the electric circuits by which the car movements are determined.

6. In electric cars, the combination of a chamber, a motor contained in said chamber, means for causing a current of air to circulate through said chamber and means for eliminating from said current iron-dust before it is introduced into said chamber.

7. In electric cars, the combination of a chamber, a motor contained in said chamber, means for causing a current of air to circulate through said chamber, and a magnetic screen past which the current circulates before reaching said chamber.

811,968. **ELEVATING DEVICE.** JOSEPH C. STIRLING, Bakerstown, Pa., assignor, by direct and mesne assignments, of two-sixths to D. W. Stirling and two-sixths to J. Ritta, Glade Mills, Pa. Filed July 25, 1905. Serial No. 271,196.



Claim.—1. In a device of the character described, the combination with a band-wheel journaled in stationary bearings and a rope carried by said band-wheel, of a track mounted above said band-wheel, said track having one end out of alinement with the other end thereof, hangers suspended upon said track and engaging said rope and means to move the hangers along the track and thereby elevate the rope.

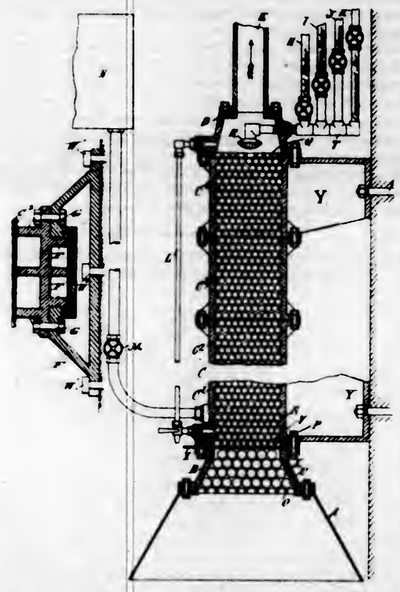
2. In a device of the character described the combination with a band-wheel and a rope carried by said band-wheel, of hangers suspended upon said band-wheel and adapted to engage said rope, a curved track arranged adjacent the band-wheel, said hangers being carried on said track and said track serving to elevate said hangers above said band-wheel, and means to move said hangers.

3. In a device of the character described the combination with a band-wheel journaled in stationary bearings, a rope passing over said band-wheel, a track arranged over the band-wheel, said track having ltaends at different levels, a hanger suspended from said track and engaging said rope, a lever arranged at a point removed from said track and connections between said lever and said hanger whereby the movement of the lever will move the hanger to different positions on the track and thereby raise or lower said rope.

4. In a device of the character described the combination of a rigid track having a raised portion, movable hangers suspended upon said track and adapted to engage a rope, means to adjustably connect the hangers together, and means to move said hangers off and on said raised portion.

811,969. **APPARATUS FOR PURIFYING AIR.** ALLAN P. SWAN, Dundalk, Ireland. Filed Dec. 17, 1904. Serial No. 287,208.

Claim.—1. In apparatus for purifying air the combination of a chamber adapted for the reception of a number of balls or spherical bodies, means for applying viscous liquid to the said bodies and means operative near the discharge end of the apparatus for effecting the cleansing of the said bodies.



2. In apparatus for purifying air, the combination of a chamber adapted for the reception of a number of balls, or spherical bodies, means for applying viscous liquid to the said bodies means operative near the discharge end of the apparatus for effecting the cleansing of the said bodies and means for conducting a current of air into and through said chamber and bodies.

3. In apparatus for purifying air, the combination of a chamber adapted for the reception of a number of balls or spherical bodies, means for applying viscous liquid to the said bodies and means operative near the discharge end of the apparatus for effecting the cleansing and the sterilizing of the said bodies.

4. In apparatus for purifying air, the combination of a chamber adapted for the reception of a number of balls or spherical bodies, means for supplying viscous liquid to the said chamber and serving the said bodies with a coating of such liquid, means operative near the discharge end of the apparatus for effecting the cleansing and the sterilizing of the said bodies and means for conducting a current of air into and through the said chamber and bodies.

5. In apparatus for purifying air, the combination of a chamber, balls or spherical bodies in the said chamber, a tank or container for viscous liquid, a pipe leading from the said tank to the chamber and a valve or diaphragm in said chamber, a conical or taper piece on the end of said chamber, a movable partition between the same and balls or spherical bodies in said conical or taper piece.

6. In apparatus for purifying air, the combination of a chamber, balls or spherical bodies in the said chamber, a tank or container for viscous liquid, a pipe leading from the said tank to the chamber, a valve or diaphragm in said chamber a conical or taper piece on the end of said chamber, a movable partition between the same and balls or spherical bodies in said conical or taper piece and means for effecting the cleansing of the balls or spherical bodies.

7. In apparatus for purifying air, the combination of a chamber, balls or spherical bodies in the said chamber, a tank or container for viscous liquid, a pipe leading from the said tank to the chamber, a valve or diaphragm in said chamber a conical or taper piece on the end of said chamber, a movable partition between the same and balls or spherical bodies in said conical or taper piece means for effecting the cleansing of the said balls or spherical bodies and means for effecting the sterilization of the said bodies.

8. In apparatus for purifying air, the combination of a chamber, balls or spherical bodies in the said chamber means for applying viscous liquid to the said bodies, and purifying media a conical or taper piece beneath said chamber, balls or spherical bodies in said conical or taper piece and a movable plate between said chamber and conical or taper piece.

9. In apparatus for purifying air, the combination of a chamber, adapted for the reception of a number of balls or spherical bodies means for applying viscous liquid to the said bodies, means operatively arranged at the discharge end of the apparatus for effecting the cleansing of the said bodies and means for rotating the said chamber.

10. In apparatus for purifying air, the combination of a chamber balls or spherical bodies in the said chamber, a tank, a pipe leading from the said tank to the chamber a conical or taper piece detachably secured to one end of said chamber, balls or spherical bodies in said conical or taper piece and a wall-bracket on said chamber.

11. In apparatus for purifying air, the combination of a chamber, balls or spherical bodies in the said chamber, a tank, a pipe leading from the said tank to the chamber a union on said pipe and a bracket on the said chamber a conical or taper piece detachably secured to one end of said chamber, balls or spherical bodies in said conical or taper piece.

12. In apparatus for purifying air, the combination of a chamber, balls or spherical bodies in the same chamber, a conical or taper piece on said chamber, balls or spherical bodies in said conical or taper piece, a movable plate interposed between the balls of the chamber and of the conical or taper piece means for applying viscous liquid to the said bodies and means for effecting the cleansing of the said bodies.

13. In apparatus for purifying air, the combination of a chamber, balls or spherical bodies in the said chamber, a conical or taper piece on the said chamber, balls or spherical bodies in the said conical or taper piece, means for shutting off the chamber from the said taper piece, means for applying viscous liquid to the said bodies and means for effecting the cleansing of the said bodies.

14. In apparatus for purifying air, the combination of a chamber, balls or spherical bodies in the said chamber, a conical or taper piece on the said chamber, balls or spherical bodies in the said taper piece, means for shutting off the said chamber from the said taper piece, a frame, a covering of coarse flannel on the said frame, means for applying viscous liquid to the said bodies and means for effecting the cleansing of the said bodies.

15. In apparatus for purifying air, the combination of a chamber, balls or spherical bodies in the said chamber, a grid or grating at the lower end of the said chamber, a conical or taper piece on the said chamber, balls or spherical bodies in the said taper piece, a grid or grating at the lower end of the said taper piece, a means for shutting off the said chamber from the said taper piece, a frame, a covering of coarse flannel on the said frame, means for applying a viscous liquid to the said bodies and means for effecting the cleansing of the said bodies.

16. In apparatus for purifying air, the combination of a chamber, balls or spherical bodies in the said chamber, a conical or dome shaped cover or cap a distributing appliance service-pipes to the said appliance for cold water, warm water, steam and compressed air, a grid or grating at the lower end of the said chamber, a conical or taper piece on the said chamber, balls or spherical bodies in the said taper piece, a grid or grating at the lower end of the said taper piece, means for shutting off the said chamber from the said taper piece, a frame, a coarse flannel covering to the said frame, and means for applying viscous liquid to the said bodies.

17. In apparatus for purifying air, the combination of a chamber, balls or spherical bodies in the said chamber, a conical or dome shaped cover or cap a grid or grating at the lower end of the said cover or cap, a distributing appliance, service-pipes to the said appliance for cold water, warm water, steam, compressed air, a grid or grating at the lower end of the said chamber, a conical or taper piece on the said chamber, balls or spherical bodies in the said taper piece, a grid or grating at the lower end of the said taper piece, means for shutting off the said chamber from the said taper piece, a frame, a coarse flannel to the said frame and means for applying viscous liquid to the said bodies.

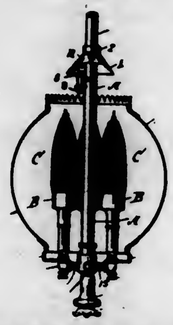
18. In apparatus for purifying air, the combination of a chamber having balls or spherical bodies of hollow formation and means for holding the said bodies in position relatively in the said chamber, means for applying viscous liquid to the said bodies and means for effecting the cleansing of the said bodies.

19. In apparatus for purifying air, the combination of a chamber having therein balls or spherical bodies of hollow formation and means for holding the said bodies in position relatively in the said chamber, means for applying viscous liquid to the said bodies, means

for effecting the cleansing of the said bodies and means for effecting the sterilization of the said bodies.

20. In apparatus for purifying air, the combination of a chamber and a conical piece thereon with balls or spherical bodies therein, means for applying viscous liquid to the said bodies and means for effecting the cleansing of said bodies.

811,970. GAS-BURNER. ROBERT SWINBURNE, New York, N. Y., and EDUARD B. HEBLER, Lyndhurst, N. J. Filed Nov. 21, 1904. Serial No. 233,626.



Claim.—1. In gas-lighting apparatus the combination with a plurality of burners one of which is constantly ignited of means to deflect the gas from a burner which is not ignited to the flame of the burner which is constantly ignited, substantially as described.

2. In a gas-lighting apparatus the combination with a constantly-ignited pilot-burner and main burners of means to deflect gas from the main burners to the pilot-flame, whereby all the main burners are simultaneously ignited, substantially as described.

3. In a gas-burner, the combination with a constantly-ignited pilot-burner and main burners of a gas-deflector provided with a vent, substantially as described.

4. In a cluster gas-light, the combination with a plurality of burners, of a globe-holder consisting of a plurality of slotted and bent arms adjustably guided on said burners, substantially as described.

5. The combination in a gas-light of burners provided with a plurality of pipes and tips and said tips having flattened sides and seats, and slotted and bent globe-holder arms seated on said seats and on said pipes, substantially as described.

6. The combination in a gas-cock of a body having a conical bore, a conical plug seated therein, a spring on the inner end of said plug and a confining-ring provided with a recess for said spring, substantially as described.

7. The combination in a gas-cock, of a body 20 provided with a conical bore and recessed spring-chamber, a conical ported plug 21 seated in said bore, a spring 22 on the inner end of said plug and bearing on the said body 20, and a recessed confining-ring 25 on said plug, substantially as described.

8. The combination in gas-lighting apparatus of a main supply-pipe, a plurality of burners connected therewith and provided with guide-seats, a rotatable adjusting device mounted on said main supply-pipe, a plurality of adjustable globe-holding arms guided on said seats, and operative connections between said arms and said adjusting device, whereby all said arms are simultaneously adjusted, substantially as described.

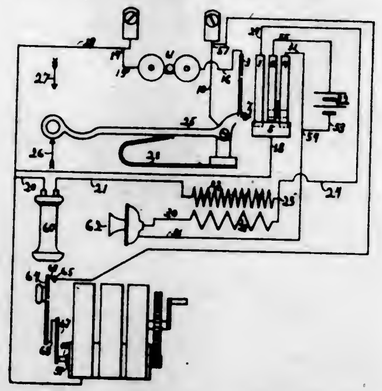
811,971. PROCESS OF MANUFACTURING MILK PREPARATIONS. SALAMON SOKOLY and EMERICH KOVÁCS, Budapest, Austria-Hungary. Filed Oct. 13, 1902. Serial No. 127,181.

Claim.—1. In the manufacture of milk preparations the subprocess of making an easily-digestible whey which is approximately germ-free from cows' milk, consisting in heating the milk to a temperature as high as possible below the coagulation-point of albumen, introducing carbonic acid at a high pressure substantially in excess of four atmospheres and agitating the milk, whereby the ingredients in suspension are precipitated, and drawing off the clear whey free from the precipitate.

2. In the manufacture of milk preparations, the process of making an easily-digestible product resembling human milk which is approximately germ-free from cows' milk, which consists in heating the same to a temperature as high as possible below the coagulation-point of albumen, introducing carbonic acid under high pressure substantially in excess of four atmospheres and agitating the milk, whereby the ingredients in suspension are precipitated, removing the carbonic acid, separating the clear whey from the precipitate, sterilizing the precipitate, and adding to the whey a sufficient percentage of the precipitate to supply the milk ingredients necessary to form the desired product.

3. In the manufacture of milk preparations the process of making an easily-digestible product resembling human milk which is approximately germ-free from cows' milk, which consists in heating the same to a temperature as high as possible below the coagulation-point of albumen, introducing carbonic acid under high pressure substantially in excess of four atmospheres and agitating the milk, whereby the ingredients in suspension are precipitated, removing the carbonic acid, separating the clear whey from the precipitate, and adding to the whey a sufficient percentage of pasteurized or sterilized milk ingredients to form the desired product.

811,972. TELEPHONE SYSTEM. ELMER A. TREPHERD, Geneseo, Ill. Filed Sept. 3, 1903. Serial No. 171,861.



Claim.—1. In a telephone set, a transmitter, a receiver, and a switch-hook, and means, including circuit connections, whereby the switch-hook, when in one position, connects said receiver and transmitter in closed local circuits, and when in another position operatively connects said transmitter and receiver to transmit and receive over the line.

2. In combination, in a telephone set, a transmitter, a receiver, and a switch-hook, means whereby said switch-hook when in one position operatively connects said transmitter and receiver for transmitting and receiving to and from the line, and means whereby the switch-hook when in another position connects said transmitter and receiver in dead closed local circuit.

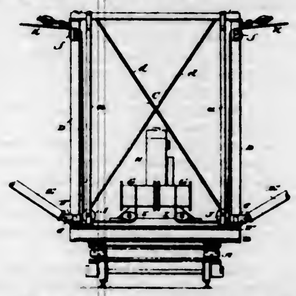
3. In combination with a telephone transmitter and receiver, a switch-hook adapted to be moved to two positions, suitable circuit connections, and contact parts controlled by the switch-hook arranged and adapted when the hook is down to short-circuit the transmitter and receiver without thereby short-circuiting the line, and when the hook is raised to operatively connect the transmitter and receiver for transmitting to and receiving from the line.

4. In combination, in a telephone set, a local battery, a transmitter, an induction-coil having primary and secondary windings, a receiver and a switch-hook, suitable circuit connections, and contact parts associated with the switch-hook, all arranged and adapted to establish when the hook is down closed local circuits, including the receiver, transmitter, and induction-coil windings, and excluding the local battery, and when the hook is raised to establish a closed local circuit including the local battery, the primary winding of the induction-coil and the transmitter, and to connect the secondary coil and the receiver for inclusion in the line-circuit.

5. In a telephone set, a transmitter, a local battery, a switch-hook, means associated with the switch-hook for control thereby arranged to establish a closed circuit including the battery and transmitter when the hook is moved in one direction, and means associated with said hook for establishing a closed local circuit including the transmitter and excluding the battery when the hook is moved in the other direction.

6. In combination in a telephone system, a switch-hook, contacts 1 and 2, arranged to be closed by the switch-hook when in raised position, contact 3 adapted to be connected with the switch-hook when the latter is in depressed position, plate 5, disposed for connection with spring 1 when the latter is freed from the hook, and contact-spring 4, arranged for connection with the plate 5 only when the hook is depressed, line binding-posts, a bell connected between spring 3 and one binding-post, a constant connection between the hook and the other binding-post, a receiver constantly connected with the first said binding-post, and connected also with spring 1, a transmitter connected to springs 1 and 4, and a local battery connected with springs 2 and 4, as and for the purposes described.

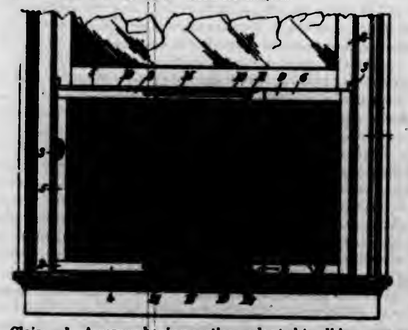
811,973. LOADER AND UNLOADER. OWEN J. TRAVIS, Denver, Colo. Filed July 27, 1905. Serial No. 271,494.



Claim.—1. In a loader and unloader, the combination of a body, a horizontally swinging or turning frame mounted on said body, an upright frame fixed to and rising from one end of said horizontally swinging or turning frame upright turn-posts mounted in the horizontally-swinging frame and the upright frame so as to rotate about their axes; said posts being arranged adjacent to opposite sides of the horizontally swinging or turning frame, booms connected to the turn-posts so as to swing horizontally with same, cables complementary to the booms for raising and lowering goods thereon, and means on the horizontally swinging or turning frame for taking up and letting out the cables.

2. In a loader and unloader, the combination of a wheel-supported body, a horizontally swinging or turning frame mounted on said body, an upright frame fixed to one end of said horizontally swinging or turning frame, upright turn-posts mounted in the horizontally-swinging frame and the upright frame so as to rotate about their axes, booms connected to the turn-posts so as to move horizontally with the posts and swing vertically independent of the same, adjustable connections intermediate the turn-posts and the booms for holding the latter against downward movement, cables complementary to the booms for raising and lowering rails or other goods thereon, and means on the horizontally swinging or turning frame for taking up and letting out the cables.

811,974. WINDOW-SCREEN. HARRY W. TUTHILL, Middletown, N. Y. Filed Nov. 15, 1905. Serial No. 287,462.



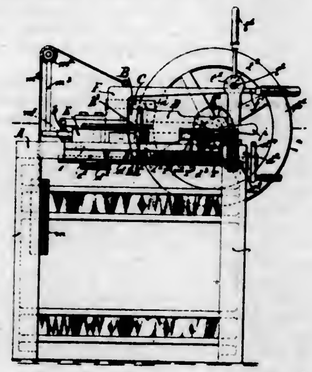
Claim.—1. A screen having sections adapted to slide one upon the other, one of said sections having slots therein, bolts carried by the opposite sections and received respectively through said slots, and sliding plates attached to one of said screen-sections and adapted to move therewith to close said slot.

2. A window-screen comprising in combination, a section having bars with slots therein, a second section having bars with bolts passing through said slots, sliding plates carried by said first bars and having openings therein receiving said bolts, whereby the movement of said bolts when said screen is extended, will extend said sliding plates.

3. A window-screen comprising in combination, a section having bars with slots therein, a second section adapted to slide thereupon and having bars with bolts passing through said slots, said first bars having grooves therein, sliding plates mounted respectively in said grooves, and having slots therein receiving said bolts.

4. A window-screen comprising in combination, a section having bars with slots therein, a second section adapted to slide thereupon and having bars with bolts passing through said slots, said first bars having grooves therein, sliding plates mounted respectively in said grooves, and having slots therein receiving said bolts, whereby the extension of said screen-sections will extend said sliding plates, and means for limiting the extension movement of said sliding plates.

811,975. MACHINE FOR BENDING ANGLE-IRONS. WILHELM VOLLMER, Winfield, N. Y. Filed Mar. 8, 1905. Serial No. 249,089.



Claim.—1. In a machine for bending angle-iron, the combination of a bed, a forming-block mounted thereon, means for bending the angle-iron against the said block, and a presser-plate hinged to said forming-block and adjustable therealong at its hinged end.

2. In a machine for bending angle-iron, a bed, a forming-block mounted thereon, a guide-block also mounted thereon, a bending-lever, a presser-plate hinged to said forming-block, and means mounted on said bed, independent of said guide-block, for adjusting the free end of said presser-plate.

3. In a machine for bending angle-iron, a bed, a forming-block mounted thereon, means cooperating with said forming-block for bending the angle-iron against the same, a presser-plate hinged to said forming-block, means for locking the free end of said presser-plate in operative position, and automatic means for returning said presser-plate to inoperative position upon the release of said locking means.

4. In a machine for bending angle-iron, a bed, a forming-block mounted thereon, means for bending the angle-iron against said forming-block, a presser-plate hinged to said forming-block and counterweighted so as to normally rest in inoperative position, and means for locking the free end of said presser-plate in operative position.

5. In a machine for bending angle-iron, a forming-block, means for bending the angle-iron against the same, a presser-plate hinged to said forming-block, standards, a shaft carried by said standards and shiftable into and out of the path of said presser-plate, and means on said shaft to position said presser-plate.

6. In a machine for bending angle-iron, a forming-block, means for bending the iron against the same, a presser-plate hinged to said forming-block, standards, and a shaft journaled in said standards and provided with a cam adapted to engage the free end of said presser-plate, said shaft being shiftable into and out of the path thereof.

7. A machine for bending angle-iron comprising in its construc-

tion a forming-block, means for bending the angle-iron against the same, a presser-plate hinged to said forming-block, standards, a brace extending between said standards, and a shaft journaled in said standards and carrying a cam adapted to coöperate with said brace in positioning the free end of said presser-plate.

8. A machine for bending angle-iron comprising in its construction a forming-block, means for bending the iron against the same, a presser-plate hinged to said forming-block, vertically-adjustable standards, and a shaft carried by said standards and provided with means to position the free end of said presser-plate.

9. In a machine for bending angle-iron, a bed, a forming-block mounted thereon, a guide-block likewise mounted thereon, a bending-lever pivoted laterally to said guide-block, and a bending-finger carried by said forming-block for retaining the horizontal flange of the angle-iron against buckling in a vertical direction.

10. In a machine for bending angle-iron, the combination of a forming-block, a pivoted bending-lever coöperating therewith, and a finger pivoted to said forming-block in the same plane as said bending-lever is pivoted, and serving to maintain one flange of the iron against buckling

11. In a machine for bending angle-iron, the combination of a forming-block, a superposed presser-plate, a bending-lever coöperating with said block and plate, and a buckle-preventing finger pivoted to said presser-plate and movable in the same direction as said bending-lever.

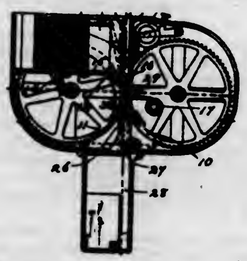
12. In a machine for bending angle-iron, a forming-block, a superposed presser-plate, means for bending the iron against said forming-block, and coöperating means carried by said forming-block and presser-plate for preventing the buckling of one flange of the angle-iron while the same is being bent.

13. In a machine for bending angle-iron, the combination of a forming-block, a superposed presser-plate, a laterally-pivoted bending-lever, and laterally-swinging buckle-preventing fingers carried by said presser-plate and forming-block.

14. In a machine for bending angle-iron, a forming-block having a laterally-swinging buckle-preventing finger the upper face of which is flush with that of said forming-block, a presser-plate superposed on said forming-block and carrying a similar finger adapted to coöperate with the first, the lower face thereof being flush with that of said presser-plate, and a laterally-pivoted bending-lever coöperating with said forming-block and presser-plate.

15. In a machine such as described, a bed, a forming-block mounted thereon and having a recess at the forming end, a laterally-pivoted bending-lever, a buckle-preventing finger laterally pivoted to said forming-block, and a foot carried by said finger and engaging the bed, said foot being movable into the recess of said forming-block.

811,976. HAND MAIL-MARKING MACHINE. HENRY B. WAITE, Newton, Mass. Filed Nov. 4, 1904. Serial No. 231,368.



Claim.—1. A hand mail-marking machine comprising an inclined chute for the letters, coöperating rotary impelling and printing segments, and a yieldable stop free to be displaced by a letter that is actuated by said segments and normally crossing the path of a letter beyond the point where the said segments first contact with a letter, whereby said stop will temporarily hold a letter in proper position during the travel of the segments prior to their taking hold of the letter, the path of the letters to said stop being entirely unobstructed.

2. A mail-marking machine comprising a rotary printing member and a rotary impression member, and a yieldable stop crossing the path of the letters beyond the point where said members first contact with a letter, whereby a letter will be arrested in position to be actuated by said members, the path of the letters to said stop being entirely unobstructed, said stop being free to be displaced by a letter that is actuated by said members.

3. A mail-marking machine comprising a rotary printing member and a rotary impression member, one of said members being yieldable relatively to the other, and a yieldable stop crossing the path of the letters beyond the point where said members first contact with a letter, whereby a letter will be arrested in position to be actuated by said members, the path of the letters to said stop being entirely unobstructed, said stop being free to be displaced by a letter that is actuated by said members.

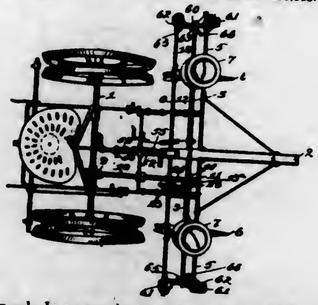
4. A mail-marking machine comprising an inclined letter-chute, a yieldable stop crossing said chute and free to be displaced by a letter that is pushed down the chute, and rotary coöperating printing and impression members mounted in positions that will bring their coacting printing and impression faces during rotation into gripping relation with a letter held by said stop, whereby the letter is fed directly by said faces.

5. In a mail-marking machine, the combination of means for supporting a stack of letters in position for feeding by one hand of the operator, and a pair of revoluble marking and carrying devices having a handle for their rotation by the other hand, said devices cooperating through an arc of subetantially from one-seventh to one-fifth of the circle of their travel, and means being provided for insuring rotation of said devices in peripheral unison.

6. A hand mail-marking machine comprising revolving feeding-grippers having printing impression and carrying surfaces, one of said surfaces being yieldable, and a yieldable stop crossing the path of a letter at a point beyond the point of coöperation of said grippers, a hopper or receptacle below the plane of the path of the letters and means for deflecting letters in a straight path from an upright to a prone position as they drop into said receptacle.

7. A mail-marking machine comprising intermeshing gears, one carrying a printing member and the other carrying an impression member, said members having gripping printing and impression surfaces in one plane, and a stop for holding a letter in position to be directly grasped by the faces of said members, said stop being free to be displaced by a letter that is actuated by said surfaces, the path of the letters to said stop being entirely unobstructed.

811,977. CORN-PLANTER. IRA A. WEAVER, Springfield, Ill., assignor to Sattley Manufacturing Company, Springfield, Ill., a Corporation of Illinois. Filed Dec. 12, 1902. Serial No. 135,013.



Claim.—1. In a corn-planter, a seedbox, a seed-plate, grooved out on the under side of its outer edge, a cut-off, and a wheel adapted to rise successively into the seed-cells, substantially as described.

2. In a corn-planter, a seedbox, a seed-plate containing seed-cells having a flaring mouth upon their inner sides, the seed-plate being grooved out on the under side of its outer edge, a cut-off, and a wheel adapted to rise successively into the seed-cells, substantially as described.

3. In a corn-planter, a seedbox, a seed-plate provided with seed-cells, a cut-off, and a plunger mounted beneath the seed-cells and in front of the cut-off, substantially as and for the purposes specified.

4. In a corn-planter, a seedbox, a seed-plate provided with seed-cells and beveled upon its lower face between the seed-cells, a cut-off, a plunger with a wheel mounted at its upper end beneath the seed-cells and adapted to rise upward and into the seed-cells and in front of the cut-off, substantially as and for the purposes specified.

5. In a corn-planter, a seedbox containing an oscillating agitator, a seed-plate provided with seed-cells, a cut-off, and a wheel adapted to rise successively into the seed-cells, substantially as and for the purposes specified.

6. In a corn-planter, a seedbox containing an oscillating agitator, a seed-plate provided with seed-cells and beveled upon its lower face between the seed-cells, a cut-off, a vertically-mounted plunger beneath the seed-cells and in front of the cut-off, substantially as and for the purposes specified.

7. In a corn-planter, a seedbox containing an oscillating agitator, a seed-plate provided with seed-cells, and beveled upon its lower face between the seed-cells, a cut-off consisting of an obliquely-mounted cut-off plunger and a vertically-mounted ejector-plunger having a small wheel mounted on its upper end beneath the seed-cells and in front of the cut-off, substantially as and for the purposes specified

8. In a corn-planter, a seedbox containing a seed-plate, a cut-off consisting of an obliquely-mounted plunger, a vertical ejector-plunger beneath the seed-plate and adapted to rise upward and into the seed-cells, an oscillating agitator mounted eccentrically to the seed-plate, substantially as and for the purposes specified.

9. In a corn-planter, a removably-mounted seedbox containing a seed-plate, a cut-off consisting of an obliquely-mounted plunger, a vertical ejector-plunger with a wheel mounted at its upper end beneath the seed-plate and adapted to rise upward and into the seed-cells, an oscillating agitator mounted eccentrically to the seed-plate, substantially as and for the purposes specified.

10. In a corn-planter, a seedbox, a shaft controlling the mechanism of the seedbox, a wheel notched on the outer edge and mounted loosely on the latter shaft, an arm keyed to the shaft and carrying a pawl mounted outside of the periphery of the notched wheel, a lever mounted between the notched wheel and the arm and engaging the pawl that the motion imparted by the driving-axle may be imparted to the mechanism of the seedbox when the lug on the check-row shaft is disengaged from the clutch mechanism, substantially as and for the purposes specified.

11. In a corn-planter, a tongue, a hand-lever, a foot-lever pivoted to the hand-lever and having a spring connected with the tongue, and a lug upon the hand-lever adapted to hold the foot-lever in engagement, substantially as and for the purposes specified.

12. In a corn-planter, a tongue, a runner-frame, a hand-lever, a foot-lever pivoted to the hand-lever and having a spring connected with the runner-frame, and a lug upon the hand-lever adapted to hold the foot-lever in engagement, the tension of the spring being adapted to be released or applied by the movement of the foot-lever, substantially as and for the purposes specified.

13. In a corn-planter, a tongue, a locking hand-lever, a foot-lever pivoted to the locking hand-lever and having a spring connection with the tongue, a lug upon the locking hand-lever adapted to hold the foot-lever in engagement, the main bar of the locking hand-lever being provided with a loop to hold the locking hand-lever and its attached plunger disengaged from the ratchet, substantially as and for the purposes specified.

14. In a corn-planter, a seedbox comprising a base-ring, a gear-plate mounted within the ring and provided with upwardly-projecting lugs, a seed-plate mounted upon and actuated by the gear-plate, an inwardly-beveled ring surrounding the seed-plate and provided with a platform, an oscillating agitator pivotally mounted underneath the platform eccentrically to the seed-plate, a cut-off mounted upon and through the platform, and a vertical roll journaled in the bracket beneath the base-ring and provided with a spring, substantially as and for the purposes specified.

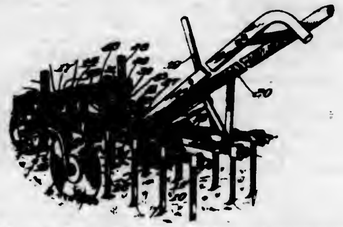
15. In a corn-planter, a check-row shaft, 12, provided with the arm 26, and lug, 27, and the depending lug, 24, and held in position by the spring, 25; the shaft, 3, provided with sprocket, 11, and clutch-sprocket, 13, a collar, 14, lugs, 15, 17, 19 & 20, spring, 21, and arm, 22, substantially as and for the purposes specified.

16. In a corn-planter, the combination of the conducting-tube 29, the hook 32 at the top of the conducting-tube, the seedbox 7 provided upon its bottom with the opening 33 adapted to fit over and receive the hook 32, the gear-plate 34 provided with depending teeth, and the pinion 37 adapted to engage with the teeth on the gear-plate 34, substantially as specified.

17. In a corn-planter, the combination of a driving-axle, a check-row shaft, a seedbox provided with a base-plate, a gear-plate, a seed-plate, containing seed-cells having beveled mouths, an oscillating agitator, a cut-off, and a vertical plunger beneath the seed-plate and operating vertically into the seed-cells, a pinion intermeshing with the gear-plate mounted on a transverse shaft and actuated by a chain-and-sprocket connection with the driving-axle, the chain-and-sprocket mechanism being connected and disconnected by a clutch mounted on the transverse shaft and alternately caught and released by a lug mounted on the check-row shaft, substantially as and for the purposes specified.

18. The combination with a movable disk having seed-cells, of means disposed underneath said disk to engage and tilt the seeds, substantially as set forth.

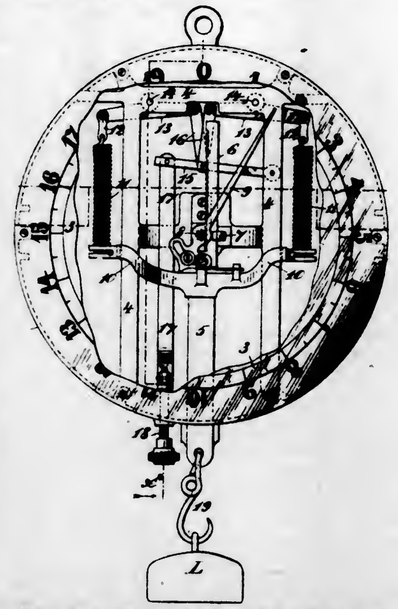
811,978. STRAWBERRY-VINE TRIMMER. NELS A. WIBORG, Cleveland, Iowa. Filed July 26, 1905. Serial No. 271,703.



Claim.—1. In a strawberry-vine trimmer, in combination, a cultivator-head, shovel-carrying members pivotally united to the head, a transverse bar resting on the head, a cutting-blade adjustably secured to the bar at each side of the head, and means for laterally swinging the shovel-carrying members.

2. In a strawberry-vine trimmer, in combination, a cultivator having a head and shovel-carrying members meeting in the head, a bolt for pivotally uniting one of such members with the head, a transverse bar resting on the cultivator-head and apertured to receive the bolt, and a cutting-blade carried by the bar.

811,979. SPRING-SCALE. OTTO C. WEISS, New York, N. Y., assignor of one-half to Oscar Mayer, New York, N. Y. Filed Dec. 31, 1904. Serial No. 239,206.



Claim.—1. A spring-scale, having two distensible spiral springs which support the load, two alike spring-levers, one arm of each being coupled to the upper end of its spring, a tare-adjusting screw, and lever mechanism between said screw and the other arms of the spring-levers for simultaneously, and uniformly lifting both springs to regulate the tare.

2. A spring-scale, having a plurality of like distensible spiral springs which support the load, like spring-levers, one for each spring and each having an arm coupled to its spring, a regulating-lever, links 16, one for each spring-lever, said links being coupled at a common point to the regulating-lever and at their other ends to the

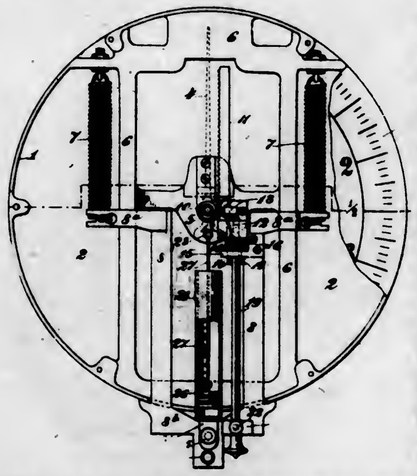
respective spring-levers, and means for adjusting the regulating-lever to bring the hand to zero on the dial.

3. A spring-scale, having a draw-bar from which the load is to be suspended, a cross-head on said bar, two like, distensible upright springs coupled below to said cross-head, two spring-levers, one arm of each of which is coupled to the upper end of one of said springs, and means for rocking or turning said spring-levers simultaneously about their respective fulcrums, for raising and lowering the springs said means comprising an intermediate lever, connecting-links, a screw, and a bar between said screw and regulating-lever.

4. A spring-scale, having a draw-bar from which the load is to be suspended, a distensible coiled spring for weighing, coupled at one end to said draw-bar, a spring-lever, one arm of which is coupled to the other end of said spring, a tare-adjusting screw, and means between said screw and the other arm of the spring-lever, for operating the last-named lever through the medium of the screw, said means comprising an intermediate lever and connecting-bar.

5. A spring-scale, having a draw-bar from which the load is to be suspended, said bar being provided with a cross-head, two upright weighing-springs 11, coupled at their lower ends to said cross-head, two spring-levers 13, provided with links 12 which couple an arm of each spring-lever to the upper end of its respective weighing-spring, a regulating-lever 15, links 16 which couple the other arms of the respective spring-levers to said regulating-lever, a tare-regulating screw 18, and a bar connecting said screw with said regulating-lever.

811,980. **SPRING-SCALE.** OTTO C. WIESE, Brooklyn, N. Y., assignor of one-half to Oscar Mayer, New York, N. Y. Filed Aug. 2, 1905. Serial No. 272,374.

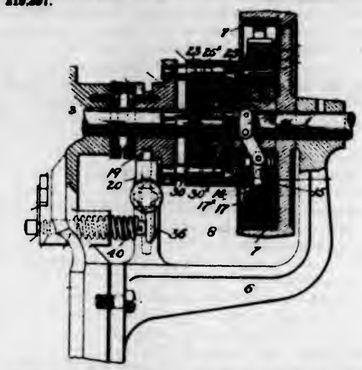


Claim.—1. A spring-scale, having a casing, a runner, a spring mechanism to which said runner is coupled, a nut-block mounted in guides on the runner, the said guides, a screw-threaded upright rod 19, mounted in bearings on the runner and screwing through said nut-block, a spring mechanism below said block, an upright rack loosely coupled to the nut-block at its lower end, a central arbor provided with a hand to traverse the scale-dial, the said dial, and a pinion on said arbor and gearing with said rack.

2. A spring-scale, having a casing, a runner, a weighing-spring mechanism to which said runner is coupled, means actuated by the runner for designating the weight of any article or thing suspended from the runner, and means for steadying and measurably retarding the vibrations of the runner in weighing, said means comprising an upright cylinder secured removably at its lower end to the runner exterior to the casing, a piston in said cylinder, and a rod connecting said piston with a fixed part of the casing at a point above the cylinder.

3. A spring-scale, having a casing, two weighing-springs therein, a U-shaped runner S, having arms S^5, to which the weighing-springs are coupled, and a tie-piece S^6, exterior to the casing, an upright cylinder 23, secured removably to the said tie-piece of the runner at its lower end, said cylinder being disposed between the upright members of the runner, a piston 26, which fits loosely in said cylinder, a rod 27, connecting said piston to a fixed part of the casing above the cylinder, and means whereby the extent of movement of the runner antagonistic to the weighing-springs designates the weight.

811,981. **DRIVING MECHANISM.** FRANK B. WILDMAN and BYARD G. LOGUE, Norristown, Pa., assignors to Mollinhaul & Wildman Manufacturing Co., Norristown, Pa. Filed Aug. 3, 1904. Serial No. 219,397.



Claim.—1. In combination, with the shaft, a pulley, a friction member fixed on the shaft, a second friction member in engagement therewith, a split-ring connection between the said second friction member and the pulley, with means for controlling the said split-ring connection, and a clutch between the said second friction member and a fixed part of the frame, substantially as described.

2. In combination with the shaft and the pulley loose thereon, a friction member secured to the shaft, a second friction member with connection between the said second friction member and the loose pulley adapted to be adjusted to connect with or disconnect the said second friction member from the loose pulley, a collar arranged to slide on the shaft, a clutch member associated with the said collar, and a clutch member fixed to a frame part, means extending from the said collar to the adjustable connection between the second friction member and the pulley, the said collar, when moved one way, setting the said adjustable connection to drive the second friction member and also to release the clutch, and when moved in the opposite direction throwing the clutch into operation and simultaneously releasing the adjustable connection of the second friction member, substantially as described.

3. In combination with the shaft and the pulley loose thereon, a collar arranged to slide longitudinally on the shaft, friction connections between the shaft and the pulley, clutch means between the shifting collar and a part of the frame and means for operating the collar, the said collar when moved in one direction controlling the friction devices to drive the shaft from the pulley and when moved in the opposite direction engaging the clutch members, the said friction devices then acting as braking means, substantially as described.

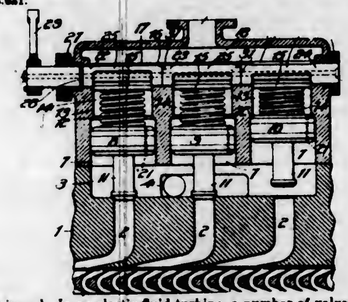
4. In combination, the pulley and its shaft, means for connecting the pulley with and disconnecting the same from the shaft, a slidable collar controlling the said connection, and a clutch also controlled by the said slidable collar, said clutch being adapted to arrest the movement of the parts when the driving connection is released, and means for operating the collar, substantially as described.

5. In combination with the shaft, a pulley loose thereon, friction devices between the shaft and the pulley, the connection between the said friction devices and the pulley, a collar slidable on the shaft with means for controlling the said connection, a clutch controlled by the collar and rendered effective when the collar is thrown back to release the driving connection whereby the friction devices will then act as a brake, the lever for operating the sliding collar and means for holding the said lever in a central position, substantially as described.

6. In combination in a driving mechanism, a shaft and pulley with friction driving elements between them, a clutch associated with said friction elements and a detachable connection between the said friction elements and the pulley, with means for controlling the parts whereby when the pulley is detached from the friction elements, the clutch is thrown in to make the said friction elements act as a brake, substantially as described.

7. In combination the shaft, a friction member fixed on the shaft, a casing, a friction-plate, said casing and plate inclosing the fixed friction member, an adjustable resilient connection between the plate and casing and means for controlling the plate and casing, substantially as described.

811,982. **CONTROLLER MECHANISM FOR TURBINES.** JAMES WILKINSON, Birmingham, Ala., assignor to Wilkinson Turbine Company, a Corporation of Alabama. Filed Jan. 26, 1905. Serial No. 243,621.



Claim.—1. In an elastic-fluid turbine, a number of valves controlling the flow of motor fluid through nozzle-passages, fluid-pressure motors to operate said valves, and secondary valves interposed between said motors and an exhaust-pressure, which cause said turbine-valves to be opened or closed by cutting their motors into or out of communication with said exhaust.

2. In a turbine, a number of nozzle-passages, fluid-pressure-controlled valves therefor, and secondary valves controlling exhaust-ports only for the valve-actuating fluid to cause the nozzle-valves to open or close in any desired manner.

3. In a turbine, a number of nozzle-passages, valves therefor, fluid-motors to actuate said valves, a port through which pressure is exhausted from each motor, and governor-controlled valves for said ports which control said nozzle-valves by regulating the exhaust from their motors.

4. In a turbine, a number of nozzle-passages, a rotor against which fluid is discharged by said passages, a number of valves for said passages, fluid-motors to actuate said valves comprising cylinders open at one end to high pressure and at the other to an exhaust, means to cause said high pressure to establish itself in the exhaust end of said cylinder, and a number of controller-valves which regulate the exhaust of pressure from said cylinders.

5. In a turbine, a number of nozzle-passages through which motor fluid is directed against a rotatable element, a number of rotary valves controlling the flow of motor fluid through said passages, and means to move said valves together, said valves being adapted to successively open or close said passages.

6. In a multiple-nozzle turbine, nozzle-passages, a set of rotary valves controlling the flow of fluid through said passages, means to move said valves simultaneously, and means to adjust said valves to produce any desired successive opening or closing of said passages.

7. In an elastic-fluid turbine, a number of nozzle-passages adapted to discharge motor fluid against a rotatable element, a set of rotary valves adjustably connected together and adapted to be moved simultaneously by hand or governor to effect any desired successive opening or closing of said passages.

8. In an elastic-fluid turbine, a number of nozzle-passages adapted to discharge motor fluid against a rotatable element, fluid-actuated valves for said passages, and a set of rotary controller-valves for controlling, by exhaust-pressure means, the operation of said nozzle-valves.

9. In an elastic-fluid turbine, a number of nozzle-passages adapted to discharge motor fluid against a rotatable element, fluid-actuated valves for said passages, controller means for said valves comprising a group of rotary valves, adapted to be simultaneously moved by a common actuator, which control by fluid-pressure means the operation of said nozzle-passage valves.

10. In an elastic-fluid turbine, a number of motor-fluid induction-passages, valves therefor, fluid-motors to operate said valves, a port for the exhaust of fluid-pressure from said motors, and a number of governor-controlled rotary valves acting to control said nozzle-valves by regulating the exhaust of fluid-pressure from their respective motors.

11. In an elastic-fluid turbine, a number of motor-fluid induction-passages, valves therefor, fluid-motors to operate said valves, ports for the exhaust of fluid-pressure from said motors which enter a common valve-chamber, and a governor-actuated valve means to successively open said ports.

12. In an elastic-fluid turbine, a number of motor-fluid induction-passages, valves therefor, fluid-motors to operate said valves, ports for the exhaust of fluid-pressure from said motors, and a multi-ported valve device adapted to successively open or close said ports, thereby controlling the operation of said first-mentioned valves.

13. In an elastic-fluid turbine, fluid-induction passages, fluid-pressure-controlled valves therefor, and a controller means comprising a multiported valve device and a number of conduits for valve-controlling fluid-pressure, the ports in said valve device and the conduits with which they are adapted to register being so arranged relatively as to produce a successive registering of said parts with said conduits, as said device is moved.

14. In an elastic-fluid turbine, fluid-induction passages, fluid-pressure-controlled valves therefor, a number of conduits for valve-controlling fluid-pressure, and a compound valve device for said conduits which has adjustable parts to effect a successive opening or closing of said conduits.

15. In an elastic-fluid turbine, fluid-induction passages, fluid-pressure-controlled valves therefor, a number of conduits for valve-controlling fluid-pressure, a compound valve device therefor having adjustable controller portions which may be set to open or close said conduits in any desired successive order.

16. In an elastic-fluid turbine, a motor-fluid-supply passage, a number of nozzle-passages leading therefrom and discharging against a rotatable element, a controller mechanism comprising a number of cylinders which communicate at one end with said supply-passage, and at the other with an exhaust-passage, valves for said nozzles, pistons for operating said valves which move in said cylinders, a multiple-valve device for successively opening communication between said cylinders and exhaust, and governor means to actuate said device.

17. In an elastic-fluid turbine, the combination with a number of nozzles, and piston-actuated valves therefor, of a fluid-pressure controller mechanism comprising a casing formed with cylinders for said pistons and with an exhaust-passage, ports leading from said cylinders to said exhaust-passage, a common valve-seat intersecting said exhaust-ports, a set of secondary valves disposed in said seat end to end, and means to actuate said latter valves.

18. In combination with a multiple-nozzle turbine having fluid-pressure-actuated nozzle-valves, a controller-casing comprising ports leading from the valve-actuating devices and communicating with an exhaust, a valve-chamber intersecting said exhaust-ports, a rotary valve-controller means in said chamber, which is removable through a side opening in said casing.

19. In combination with a multiple-nozzle turbine having fluid-pressure-actuated nozzle-valves, a controller-casing comprising ports leading from the valve-actuating devices and communicating with an exhaust, a valve-chamber intersecting said exhaust-ports, a number of rotary valves disposed end to end in said chamber, means to actuate said valves, and means to adjust them to open and close said exhaust-ports successively.

20. In an elastic-fluid turbine, a number of induction-nozzles, piston-actuated valves for said nozzles, cylinders for said pistons exposed below to the motor-fluid pressure and above to an exhaust through valve-controlled ports, means to provide for the slow admission of high pressure above said pistons, springs tending to seat said valves, a number of controller-valves for the exhaust of said cylinders, and a common actuator for said controller-valves which moves them simultaneously.

21. In an elastic-fluid turbine, a motor-fluid-supply chamber, a plurality of induction-passages leading from said chamber and adapted to discharge the fluid against a rotatable element, a controller-casing provided with a number of cylinders, pistons therein exposed below to the pressure in said supply-chamber, means to permit a restricted flow of said high pressure above said pistons, valves operated by said pistons for controlling the flow of fluid through said passages, springs tending to close said valves, and a number of secondary valves which control the operation of pistons by regulating the exhaust of pressure from the cylinders above them.

22. In an elastic-fluid turbine, a number of fluid-induction passages and piston-actuated valves therefor, in combination with a controller mechanism comprising an exhaust-passage, a number of ports communicating therewith and with the cylinders for said pistons, a number of similar valves for opening and closing said exhaust-ports,

means to adjust the position of said latter valves relatively to each other, and governor-controlled means to actuate them.

13. In an elastic-fluid turbine, a rotary valve controlling the

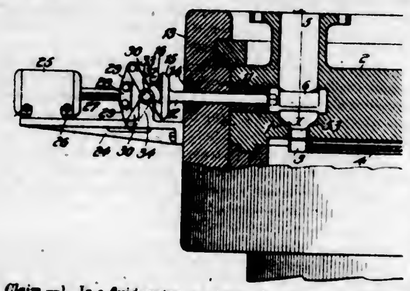
separate wheel-compartments in combination with fluid streams for

adapted to hold the latter to their support by being shrunk thereon

means to adjust the position of said latter valves relatively to each other, and governor-controlled means to actuate them.

23. In a controller-casing for a number of nozzle-valves, motors for actuating said valves, exhaust-passages leading from said motors through the controller-casing to an exhaust-pressure, a number of rotary valves adjustably connected to each other, a seat for said valves leading through said casing and intersecting said passages, and means to operate said valves.

811,983. VALVE MECHANISM FOR FLUID-MOTORS. JAMES WILKINSON, Birmingham, Ala., assignor to Wilkinson Turbine Company, a Corporation of Alabama. Filed Feb. 2, 1905. Serial No. 243,883.



Claim.—1. In a fluid-motor, a rotary valve, a power device for moving said valve, and motion-transmission means between said valve and actuator which increase the power of the latter in moving said valve against an opposing force.

2. In a motor, a rotary fluid-pressure valve, a port or passage controlled by said valve, an actuator adapted to move said valve with increasing power, and means to enable said actuator to positively force said valve against its seat to close said port or passage.

3. In a motor, a rotary valve for a fluid-conduit, a shoulder on said valve, a stop adapted to engage said shoulder to arrest the travel of said valve after it has assumed a closed position, and power devices to force said valve against its stop and seat.

4. In a motor, a rotary fluid-pressure valve controlling a fluid port or passage, an actuator connected through power-increasing devices to said valve, and means, to stop the travel of said valve when it has closed said port or passage, which acts, as a fulcrum, against which said actuating devices force said valve to hold it against its seat.

5. In a motor, a rotary motor-fluid valve, an adjustable stop to arrest the movement of the valve as it assumes its closed position, and valve-operating mechanism which acts against said stop, as a fulcrum, to force said valve against its seat.

6. In a motor, a rotary motor-fluid valve, and a toggle-press for actuating said valve with variable speed and power against resistance and forcing it against its seat.

7. In an elastic-fluid turbine, a rotary motor-fluid valve, a reciprocatory actuator for said valve, a gear transmission means between said actuator and valve and an adjustable stop for said valve.

8. In a motor, a fluid-passage, a rotary valve therefor, a toggle-press, and gear means to transmit motion from said toggle-press to said valve.

9. In an elastic-fluid turbine, a nozzle-passage having a radially-elongated admission end and a peripherally-elongated discharge end which covers a section of a set of buckets mounted upon a rotating element, in combination with a substantially radially disposed rotary valve for controlling the flow of fluid-pressure through said nozzles.

10. In a turbine, a nozzle-passage having an entrance which is radially elongated and an intermediate portion which is contracted radially and gradually elongated peripherally to its discharge end which corresponds substantially in radial width with a set of rotatable buckets, and a rotary valve for controlling the flow of motor fluid through said nozzles.

11. In an elastic-fluid turbine, a rotary motor-fluid valve, and a reciprocating actuator therefor which moves in the direction of the axis of rotation of said valve, said valve and actuator being disposed substantially radially to the axis of rotation of the turbine.

12. In a multistage turbine, a rotary nozzle-valve, a reciprocating motor for actuating said valve which is disposed in substantial axial alinement with said valve.

13. In an elastic-fluid turbine, a rotary valve controlling the flow of motor fluid against a rotatable element, a reciprocating actuator for said valve disposed end to end therewith, and transmission means between said valve and actuator whereby the latter's lineal movement is converted into rotary motion and applied to the former to fully open and close the same.

14. In a turbine, a nozzle-passage, a substantially radially disposed rotary valve therefor which is operated by a gear device at one end thereof, and a fluid-motor for actuating said gear means and controlling the operation of said valve.

15. In a turbine, a nozzle-passage, a substantially radially disposed rotary valve therefor provided with gear-teeth at one end, and a valve-operating mechanism comprising a toothed element which meshes with the toothed end of said valve for rocking the same.

16. In an elastic-fluid turbine, a diaphragm-partition, a fluid-conduit between stages leading through said diaphragm, a rotary valve for said conduit having its inner end provided with gear-teeth, and gear means meshing with said valve-gear and driven by a power device disposed within the turbine.

17. In a multistage turbine, a rotary stage-valve, an actuator therefor within the turbine, and a lever connection between said actuator and valve which moves in a plane substantially parallel with that of a diaphragm-partition.

18. In a motor, a fluid-passage, a valve therefor, a power device to operate said valve, and toggle means for transmitting motion from said device to said valve which comprise a pair of levers journaled on a stationary axis, toggle-links connecting said levers to said power device, and gear means to transmit motion from said levers to said valve.

19. In a turbine divided into wheel-compartments by diaphragms, a fluid-conduit between wheel-compartments, a rotatable valve for said conduit, and an actuator for said valve comprising a cylinder carried by said diaphragm, a piston and its rod which travel substantially radially from the turbine-shaft, one or more toothed levers pivotally mounted on the diaphragm and connected to said rod, and gear means for rocking said valve which mesh with said toothed lever or levers.

20. In an elastic-fluid turbine, a diaphragm-partition, a rotary valve seated in a shoulder of said diaphragm and controlling a stage-nozzle passage, a fluid-motor mounted on said diaphragm and having a radially-movable piston-rod, a gear driven by said rod and meshing with a gear connected to said valve, and antifriction means to take up the end thrust of said gear on said valve.

21. In a motor-fluid, a rotary fluid-pressure valve, a reciprocating motor movable axially with relation to said valve and connected to one end thereof, and an antifriction thrust-bearing for the other end of said valve.

22. In a fluid-motor, a rotary fluid-pressure valve, a reciprocating motor movable axially with relation to said valve and connected to one end thereof, and an adjustable antifriction thrust-bearing for the other end of said valve.

23. In a turbine, a diaphragm, a rotary valve seated therein, a motor for operating said valve connected to one end thereof, a screw-plug inserted in said diaphragm opposite the other end of said valve, a ball-race in said plug, and balls therein which engage said valve end.

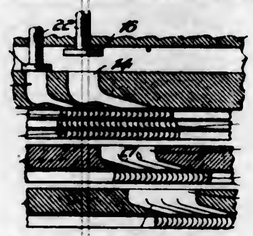
24. In an elastic-fluid turbine, a conduit through which motor fluid is adapted to flow against a rotatable element, a rotatable valve therefor, means for moving said valve which projects outside of the turbine, and a reciprocating motor disposed without the turbine and connected to said stem.

25. In an elastic-fluid turbine, a diaphragm-partition dividing the turbine into wheel-compartments, strengthening-webs leading radially from the center of the diaphragm to or near its periphery, valves for motor-fluid passages, and actuating devices therefor which are mounted on the diaphragm between said webs.

811,984. ELASTIC-FLUID TURBINE. JAMES WILKINSON, Providence, R. I., assignor to Wilkinson Turbine Company, a Corporation of Alabama. Filed May 23, 1905. Serial No. 261,676.

Claim.—1. In an elastic-fluid turbine, a working passage for the motor fluid therein comprising successive rows of rotating buckets, means to deliver the motor fluid at greater velocity to the first row or rows of buckets than to the succeeding rows, and means to discharge fluid from said buckets subjected to the higher velocities, said means consisting of openings of substantially the same cross-sectional area as the initial fluid-supply openings, for the purposes described.

2. In a turbine, rows of nozzles coöperating with rows of revolving buckets, bucket-wheels supporting said buckets and disposed in separate wheel-compartments in combination with fluid streams for moving said buckets, means to cause the streams to act with greater velocity on the first row or rows of buckets than on the succeeding rows, and independent valves for cutting said streams into and out of service, said nozzles being so proportioned for the first stages that when said valves are open, the row or rows of buckets in the first wheel-compartment are substantially cut out of service.



3. In a turbine, the provision of a velocity-stage compartment, motor-fluid supply and discharge openings therefor of substantially the same cross-sectional area, rotatable buckets therein, means to control the supply of motor-fluid to said compartment, and a working passage comprising stationary guide devices for the fluid and interposed rows of rotating buckets into which passage the motor fluid flows from said velocity-stage compartment and in which the velocity developed in its passage through the turbine is abstracted.

4. In a turbine, a compartment and means therein for fractionally abstracting velocity from fluid-pressure and converting it into rotary motion, fluid supply and discharge ports for said compartment of substantially the same cross-sectional area, valve means to vary the supply of fluid to said compartment, and one or more compartments having means therein to further abstract velocity from the fluid-pressure discharged from said first-mentioned compartment.

5. In a multistage turbine, supply-nozzles and coöperating buckets for each stage adapted to drive the turbine under normal-load conditions, the supply nozzle or nozzles for the initial stage being adapted to convert a greater per cent. of the fluid-pressure into velocity than the succeeding nozzles and one or more overload-nozzles adapted to discharge fluid-pressure, to compensate overload conditions, into said initial stage, the cross-sectional area for the discharge opening or openings for said stage corresponding substantially with the combined cross-sectional area of the nozzles supplying fluid-pressure thereto.

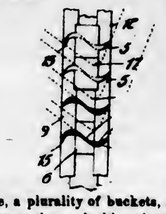
6. In a turbine having a plurality of separate compartments to which the fluid-pressure is delivered in succession, nozzle-passages connecting said compartments and rotatable buckets within said stages which coöperate with said nozzle-passages and convert fluid velocity into mechanical power, in combination with a plurality of nozzles for admitting an overload supply of pressure to the turbine, said overload-nozzles being equal in number with the supply-passages for the compartments into which they discharge, but of less capacity.

7. In a multistage turbine in which the fluid-pressure is fractionally expanded, the combination with a supply-nozzle for an initial stage, of an overload supply-nozzle arranged in juxtaposition to said supply-nozzle, and a discharge-opening from said initial stage formed by a nozzle-passage leading to a succeeding stage, said nozzle-passage being disposed in line with the fluid streams flowing through said supply and overload nozzles and being of a capacity calculated to cause the motor fluid to flow through the said initial stage without material driving effect upon the buckets therein when the overload-nozzle is in service.

8. In a multistage turbine having a plurality of supply-nozzles for an initial stage designed to admit sufficient fluid to drive the turbine up to its full load capacity, the combination with a plurality of overload supply-nozzles designed to admit an additional supply of motor fluid to said initial stage, said overload-nozzles being of smaller capacity than the supply-nozzles and arranged each in close relationship with a supply-nozzle, and stage-nozzle passages leading from said initial compartment and communicating with a succeeding stage.

811,985. TURBINE BUCKET-WHEEL. JAMES WILKINSON, Providence, R. I., assignor to Wilkinson Turbine Company, a Corporation of Alabama. Filed July 3, 1905. Serial No. 268,286.

Claim.—1. In a turbine, a plurality of buckets, a support therefor, and a locking-ring engaging said support and said buckets and adapted to hold the latter to their support by being shrunk thereon, substantially as described.



2. In a turbine, a plurality of buckets, a support upon which said buckets are mounted, two locking-rings disposed on opposite sides of the support and in engagement therewith, the said rings being adapted to engage said buckets and to lock the same to said support by being shrunk, and means to fasten the rings to the bucket-support, substantially as described.

3. In a turbine, a plurality of buckets, a support therefor, and means to fasten said buckets to said support by shrinking an element or elements which engage both buckets and support.

4. In a turbine, a plurality of buckets, a support therefor, a locking element which engages said support and buckets and is adapted to lock these parts together by being shrunk, and means to fasten said elements to the bucket-support.

5. In a turbine, a plurality of buckets, a support therefor, locking elements which engage said support and buckets and are adapted to lock these parts together by being shrunk, and means to fasten said elements to the bucket-support.

6. A turbine bucket-wheel formed with a flanged rim portion, buckets having flanged base portions engaging said rim, and a ring formed with shoulders adapted, when the ring has been shrunk, to engage the rim of said wheel and the flanged bases of said buckets, a clearance being left between the ring-shoulders and buckets or rim to provide for this shrinkage, and means to secure said ring to said wheel.

7. A turbine bucket-wheel, buckets, said wheel and buckets having portions adapted to be engaged by locking means, said locking means comprising two rings adapted to be shrunk into engagement with the wheel and buckets, and bolts or rivets for securing said rings to the wheel.

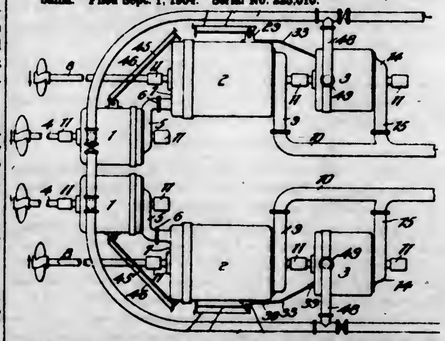
8. In a turbine, a bucket-support, and buckets thereon having reversely-disposed impact-surfaces, the reverse side of the bucket opposite a concave impact-surface being convex and of greater thickness than the middle portion of the bucket.

9. In a turbine, a bucket formed on a double curve, thickest at the bends of the curve and tapering to the sides and center.

10. In a turbine, a plurality of buckets 5, and a support therefor, substantially as described.

11. In a turbine, a bucket having duplicate reversely-disposed impact-faces in the form of double curves, meeting at the bucket edges and arranged so as to leave metal of varying thickness between them at different parts of the bucket.

811,986. MARINE TURBINE. JAMES WILKINSON, Birmingham, Ala., assignor to Wilkinson Turbine Company, a Corporation of Alabama. Filed Sept. 1, 1904. Serial No. 223,010.



Claim.—1. In a set of marine turbines, a high-pressure, two-speed, forward-driving turbine, and a low-pressure turbine operat-

ing in series therewith, independent shafts for said turbines, and a reversing-turbine connected to one of said shafts.

2. In a set of marine turbines, a high-pressure multicellular turbine having full and cruising speed working passages, a shaft therefor, a turbine adapted to operate in series with said high-pressure turbine, a shaft therefor, and a high-pressure reversing-turbine connected to one of said shafts.

3. In a set of marine turbines, a high-pressure turbine having working passages for driving a shaft at full and cruising speeds, a turbine connected up in series therewith, a separate shaft for said latter turbine, and an independent reversing-turbine connected to said latter shaft.

4. The combination with a forward-driving turbine and a reversing-turbine, of one or more valve-controlled nozzle-passages for each turbine, and a common controller mechanism for regulating the admission of motor fluid to said turbines.

5. The combination with a forward-driving turbine having a plurality of admission-nozzles, and a reversing-turbine having a plurality of admission-nozzles, of a fluid-pressure-controller mechanism adapted to control the admission of motor fluid to one of said turbines while cutting said other turbine out of service.

6. The combination in a set of turbines, of a forward-driving turbine, a reversing-turbine, motor-fluid-admission passages for each of said turbines, fluid-pressure-actuated means to open and close said passages, and a controller mechanism having conduits leading to the said fluid-actuated means of both turbines, said mechanism being adapted to close the admission-passages for one turbine and to control the opening of the admission-passages for the other.

7. In a set of marine turbines, the combination of two forward-driving turbines operating in series and connected to different shafts, and a reversing-turbine, with a controller means adapted to control the operation of the set of turbines by regulating the flow of motor fluid between the turbines connected in series and the admission of motor fluid to the reversing-turbines.

8. The combination of a forward-driving and a reversing-turbine both connected to a common shaft, with a common controller mechanism comprising fluid-actuated means to vary the admission of motor fluid to said turbines, a fluid-pressure-controller chamber, conduits leading therefrom to said several fluid-actuated means, and valve means operating to admit different fluid-pressures to said conduits to control the operation of said means and cut one of said turbines out of service, and to control the admission of motor fluid to the active turbine.

9. In a fluid-pressure-controller mechanism for a set of turbines, a plurality of fluid-pressure-admission nozzles for each turbine, fluid-actuated means to open and close said nozzles, conduits to connect said means with a controller-chamber, and valve means in said chamber adapted to control the admission of motor fluid to one of said turbines while cutting it off from the other, substantially as described.

10. In a fluid-pressure-controller mechanism for two independent turbines, motor-fluid-supply passages for said turbines, fluid-pressure-actuated valves to open and close said passages, conduits for conducting controller fluid-pressure to the valves of said turbines, and a controller-valve means to open said conduits to a high or low pressure to cause the valves which they control to open or close.

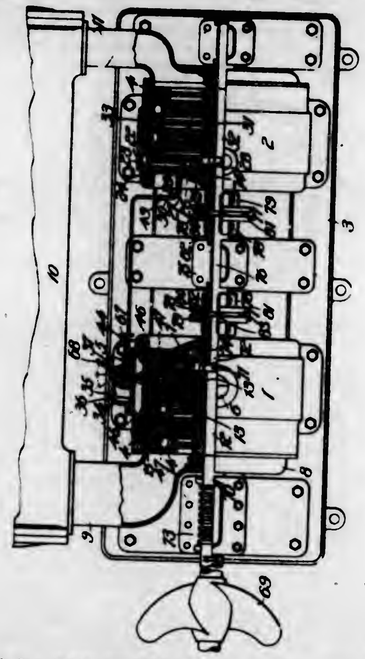
11. The combination of a turbine, and a fluid-pressure-controller means therefor, with a reversing-turbine, fluid-actuated valves therefor, and conduits leading from said controller means to said valves, said means being adapted to control the valves of said reversing-turbine in one operating position, when it cuts off the supply of fluid-pressure to said first-mentioned turbine.

12. In a set of marine turbines, a shaft, a forward-driving and a reversing-turbine connected to said shaft, a plurality of supply-valves and nozzles for each turbine, and a common controller means for the supply-valves of both turbines.

811,987. MARINE TURBINE. JAMES WILKINSON, Birmingham, Ala., assignor to Wilkinson Turbine Company, a Corporation of Alabama. Filed Sept. 15, 1904. Serial No. 224,886.

Claim.—1. In a fluid-controller means for a turbine, fluid-controlled means to open and close nozzle-passages, pipes communicating with said means and disposed within a reduced portion of the turbine-casing, a fluid-controller chamber, and conduits leading therefrom which are detachably connected to said pipes.

2. In a turbine having an inner casing and a removable outer casing, fluid-pressure-controlled valves within the turbine, fluid-conducting pipes seated in the same or different cut-away portions of the inner casing and adapted to admit a high or low pressure to said valves, a controller-valve controlling the admission or exhaust of pressure to other pipes which are coupled to the first-mentioned pipes.



3. In a turbine having an inner casing and a removable shell surrounding it, nozzle-passages, valves therefor, motors to actuate the valves, conduits leading to said motors through the casing, pipes communicating with said conduits and disposed in a reduced portion of said casing so as to be below or flush with its outer periphery, and a fluid-controller means carried by said shell and adapted to control the admission of fluid-pressure to said pipes.

4. The combination with a turbine having an inner casing and an outer shell, a recess in said casing, one or more pipes disposed therein, a controller-chamber, pipes leading therefrom through said shell, means to couple said latter pipes to the pipes in the casing, and means, controlled by the pressure in said pipes which regulate the operation of the turbine.

5. In a turbine, a supply-head for a wheel-compartment, a valve-chamber therein leading inwardly from its outer periphery, a valve-seat disposed in the outer end of said chamber and communicating with a motor-fluid-supply chamber, a valve in said valve-chamber, a nozzle-passage leading therefrom through said head, a fluid-motor for operating said valve comprising a cylinder formed by the inner end of said chamber, a piston therein for operating said valve, and means to communicate a controller-fluid pressure to said cylinder.

6. In a supply-head for a wheel-compartment, a chamber therein leading from its periphery inwardly, a partition therein, a valve having a stem passing through said partition and connected to a piston, a fluid-supply opening adapted to be closed by said valve, a nozzle-passage supplied with motor-fluid pressure when said opening is open, means tending to move said valve in one direction, and controller means exposing said piston to a pressure which will cause it to move in the opposite direction.

7. In a turbine, a supply-valve, a chamber for said valve leading radially into the valve-bearing portion, a supply-passage communicating with the outer end of said chamber, a circular valve-seat inserted in the outer end of said chamber, a nozzle-passage communicating with said chamber, a piston connected to said valve and movable in the inner end of said chamber as a cylinder, means to admit a high pressure against said piston to close said valve, and controller means to open said valve.

8. In a turbine, a plurality of supply-valves, a valve-bearing portion, radial chambers therein within which the valves are disposed and from which lead nozzle-passages, pistons for actuating said valves, a motor-fluid-supply chamber, valve-seats at the outer end of said chambers through which motor fluid enters from said supply-chamber, passages to expose said pistons to a high pressure tending to close said valves and a controller-fluid pressure tending to open them, and springs cooperating with said latter pressure to open the valves.

9. In a controller means for a turbine, a chamber to which high pressure is admitted, a multiported valve-seat, a valve thereon held to its seat by said chamber-pressure, means to unbalance said valve by admitting low or atmospheric pressure between it and its seat, and conduits leading from the ports in said seat to valve means which control the discharge of motor fluid against rotating buckets in the turbine.

10. In a controller means for a turbine, a chamber to which high and low pressures are admitted, a valve therein exposed to said pressures and unbalanced thereby, a seat to which said valve is firmly held by said pressures, passages leading to said chamber, said valve being adapted to admit said low pressure to said passages in groups, independent sets of nozzle-passages controlled by said groups of passages and adapted to be cut out of service when said low pressure is admitted to their respective groups of passages, and means to admit high pressure to one group of passages to open one or more of the nozzle-passages of a set.

11. In a turbine having a plurality of fluid-pressure-controlled valves, a controller mechanism comprising a plurality of conduits for the valve-controlling fluid which lead from a controller-chamber, a valve therein adapted to open a part of said conduits to the admission of a low pressure, and a controller device adapted to control the admission of high pressure to the other of said conduits.

12. In a turbine having a plurality of fluid-actuated valves, a controller mechanism therefor comprising a plurality of conduits for valve-actuating fluid opening into a controller-chamber, a multi-ported valve therein to control the admission of low pressure to said conduits in groups, and a slide-valve acting between high and low pressures and operating successively to admit one or the other of said pressures to the conduits of a group.

13. A controller mechanism for a multiple-valve turbine comprising a controller-chamber formed in a movable casing and exposed to high pressure, a plurality of passages which communicate with said chamber and conduct fluid-pressure therefrom to control the operation of a set of turbine-valves, a second set of independent turbine-valves, one or more chambers in said casing in communication with a low or atmospheric pressure, and a plurality of passages which communicate said latter pressure to the latter set of turbine-valves.

14. In a controller mechanism for a turbine, a multiported casing, a multiported valve-shell with ports which are adapted to register with different groups of ports in said casing, one or more recesses in said shell which are exposed to a low or atmospheric pressure and which are adapted to communicate with the group or groups of ports in said casing which are not in register with the ports in said shell, a plurality of turbine-valves and means to control their operation comprising motors, passages connecting said motors with the ports in said casing, and means to cause said valves to close when their motors are exposed to a low pressure through said passages.

15. In a controller mechanism for a turbine, a chamber supplied with high pressure, a multiported valve-seat therein, a valve-shell mounted and movable on said seat and provided with a set of ports, means to admit high and low pressure to said shell, means to adjust said shell to move its ports into register with a set of ports in said seat, means to admit the high or low pressure in said shell to one or more of the ports therein, said shell acting as a valve to admit low pressure to the ports in said seat not in register with its ports, and means to connect the ports in said seat with fluid-pressure-controlled means to vary the fluid-pressure supply to the turbine.

16. In a turbine, groups of working passages at different distances from the shaft-center, means to cut said working passages out of service comprising valves, actuating-pistons therefor, cylinders for said pistons, spring means tending to move said valves to their closed position in nozzle-passages which they control, and means to admit a controller-fluid pressure to said chambers comprising a plurality of conduits and a controller-valve adapted to admit a low or atmospheric pressure to the motor-cylinders of the valves for one set of working passages, in combination with means to admit high or low pressure to the motor-cylinders of the other working passages.

17. In a controller mechanism for a turbine, a controller-pressure chamber, a multiported valve-seat therein, and a valve-shell adapted to control the admission of high or low pressure to the ports in said seat in groups, said shell comprising a plurality of ports to which a high or low pressure is admitted by a controller-valve, and a plurality of chambers exposed to a low or atmospheric pressure and adapted to communicate with the ports in the seat not in register with the ports in said shell, in combination with fluid-pressure-actuated means within the turbine to vary the flow of motor fluid.

18. In a set of turbines driving a common shaft, a bearing for said shaft between said turbines, and means, interposed between said bearing and the turbines, to prevent, by a forced circulation of air, the conduction of excessive heat to said bearing.

19. In a compound turbine, a plurality of separate shells, a shaft, one or more bucket-bearing elements in each shell which are connected to said shaft, a bearing for said shaft, between two of said shells, and ventilated couplings in said shaft to prevent the conduction of heat from the shells to said bearing.

20. In combination with a turbine, a shaft therefor, a bearing for said shaft, a coupling interposed between the turbine and bearing, and means to prevent the heat of the shaft portion in the turbine being transmitted through said coupling to said bearing.

21. In combination with a turbine, a shaft formed in two parts, one entering the turbine and driven thereby which becomes highly heated by the temperature of the motor fluid in the turbine, the other mounted in the bearing, and a coupling adapted to be cooled by the circulation of air, which connects said parts of the shaft together.

22. In combination with a turbine, a sectional shaft, a bearing in which one section of said shaft is supported, said other section being disposed within the turbine, and means to connect the shaft-section together and leave an air-space between their adjacent ends, as and for the purposes described.

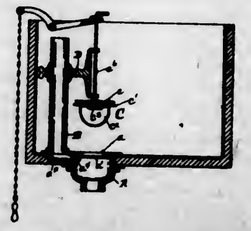
23. In combination with a turbine, a sectional shaft therefor, one section being subjected to the heat within the turbine, a bearing in which the other section is supported, flanged portions carried by the adjacent ends of said sections, means to connect said portions to couple the shaft-sections together, shoulders on the abutting faces of said flanged portions which set them apart to form an air-space between them.

24. In combination with a turbine, a sectional shaft therefor, a coupling connecting the sections of said shaft and disposed between the turbine and a bearing for the shaft, said coupling comprising collars rigidly connected to an end of each shaft and to each other, and air-passages formed in and between said collars and so arranged that the coupling acts, when rotated, with centrifugal effect to maintain a cooling circulation of air which prevents the conduction of heat through the coupling to said bearing.

25. A turbine, a sectional shaft therefor, a bearing for said shaft, and means to connect the sections of the shaft, which comprise two collars each having a hub portion keyed to an end of a shaft-section, bolt-holes leading through circular shouldered portions of said collars, bolts which connect said collars, said shoulders being adapted to abut so as to leave a clearance between the collars, and air-passages leading through said hub portion of a collar, said shaft-sections being reduced when they abut.

26. The combination of a motor, a shaft driven thereby, a bearing for said shaft disposed without the motor, and means interposed between the motor and bearing to prevent the conduction of heat through said shaft from the motor to said bearing by inducing currents of air between parts of said shaft.

811,988. FLUSHING-VALVE. CHARLES F. WHITE, Hamilton, Ohio, assignor to Michael D. Heilrich, Evansville, Ind. Filed June 30, 1905. Serial No. 267,893.



Claim.—1. In a flushing-valve the combination of a valve-seat consisting of a flange surrounding an opening, a valve consisting of a disk to contact the valve-seat and a buoyant member situated below the disk and being of a diameter such as to pass through said opening.

2. In a flushing-valve the combination of a cup adapted to be

seated in the bottom of a flushing-tank having an internal annular flange near its top forming a valve-seat, a means for coupling the

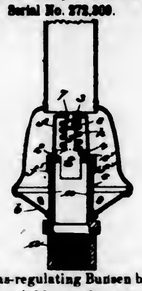
8. In a gas-regulating Bunsen burner, the combination with the

3. In a condenser vacuum-breaker, the combination with th

seated in the bottom of a flushing-tank having an internal annular flange near its top forming a valve-seat, a means for coupling the flushing-pipe to its bottom and a valve consisting of a disk to seat against the flange, and a buoyant member located beneath the disk and of a size such as to pass through the flange into the cup.

3. In a flushing-valve the combination of a casting in the shape of a cup to be seated in the bottom of a flushing-tank and having near its top an interior annular flange together with a valve consisting of a metallic disk to seat against the valve-seat and a ball below the disk of a diameter which is to pass through the annular flange into the cup.

811,989. **GAS-REGULATING BUNSEN BURNER.** CHARLES B. WHITE, Waterbury, Conn., assignor to The Plume and Atwood Manufacturing Company, Waterbury, Conn., a Corporation of Connecticut. Filed Aug. 5, 1905. Serial No. 272,809.



Claim.—1. In a gas-regulating Bunsen burner, the combination with the nipple, of a revoluble member surrounding the upper end thereof and within the Bunsen burner and revoluble therewith, an internal valve-spring actuated in one direction and guided by the nipple, and means actuated by the movement of the revoluble member for actuating the valve in the other direction for controlling the supply of gas.

2. In a gas-regulating Bunsen burner, the combination with the nipple, of a revoluble member surrounding and extending above the upper end thereof so as to form an internal chamber, and which revoluble member is within the Bunsen burner and is revoluble therewith, an internal valve contained within said chamber and guided by the nipple, and means actuated by the movement of the revoluble member for actuating the valve for controlling the supply of gas.

3. In a gas-regulating Bunsen burner, the combination with the nipple, of a revoluble member surrounding the upper end thereof and within the Bunsen burner and revoluble therewith, an internal valve guided by the nipple and located between the same and the said revoluble member, and means actuated by the movement of the revoluble member for imparting a longitudinal axial movement to the valve for controlling the supply of gas

4. In a gas-regulating Bunsen burner, the combination with the nipple having an elongated perforation in its upper end, of a revoluble member surrounding and extending beyond the upper end thereof and having a central hole and forming an internal chamber, a valve located therein and having a body extending down into the perforation of the revoluble member, and means for actuating the valve.

5. In a gas-regulating Bunsen burner, the combination with the nipple having an elongated perforation in its upper end, of a revoluble member surrounding and extending beyond the upper end thereof and having a central hole and forming an internal chamber, a valve located therein and having a body extending down into the perforation of the nipple and up into the perforation of the revoluble member, and opposite vertically-disposed circular cams for actuating the valve with the turning of the revoluble member.

6. In a gas-regulating Bunsen burner, the combination with the nipple having an elongated perforation in its upper end and a revoluble member surrounding and extending beyond the upper end thereof and having a central hole and forming an internal chamber, of a valve comprising a body portion *g*, shoulders 4, stem 5, conical head 6 and a square and recessed upper end 7.

7. In a gas-regulating Bunsen burner, the combination with the nipple having an elongated perforation in its upper end and a revoluble member surrounding and extending beyond the upper end thereof and having a central hole and forming an internal chamber, of a valve comprising a body portion *g*, shoulders 4, stem 5, conical head 6, and a square and recessed upper end 7, and a helical spring in said chamber around the upper end of said valve with one end bearing on the under surface of the revoluble member and the lower end on the shoulders of said valve.

8. In a gas-regulating Bunsen burner, the combination with the nipple having an elongated perforation in its upper end and a revoluble member surrounding and extending beyond the upper end thereof and having a central hole and forming an internal chamber, of a valve comprising a body portion *g*, shoulders 4, stem 5, conical head 6 and a square and recessed upper end 7, and opposite vertically-disposed circular cams formed with the revoluble member and adapted to come beneath the shoulders of the valve.

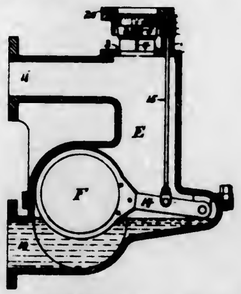
9. In a gas-regulating Bunsen burner, the combination with the nipple having an elongated perforation in its upper end and a revoluble member surrounding and extending beyond the upper end thereof and having a central hole and forming an internal chamber, of a valve comprising a body portion *g*, shoulders 4, stem 5, conical head 6 and a square and recessed upper end 7, opposite vertically-disposed circular cams formed with the revoluble member and adapted to come beneath the shoulders of the valve, and a helical spring *h* surrounding the valve at one end bearing upon the shoulders thereof and at the upper end bearing upon the upper side of the revoluble member and acting to keep the valve down to its seat or against the surfaces of said cams.

10. In a gas-regulating Bunsen burner, the combination with the nipple, of a revoluble member surrounding the upper end thereof and extending above the same so as to form a valve-receiving chamber, a spring-returned valve inclosed and surrounded by the revoluble member and located between the same and the upper end of the nipple and coacting devices for actuating the valve for controlling the supply of gas.

11. In a gas-regulating Bunsen burner, the combination with the nipple, of a revoluble member surrounding the upper end thereof and extending above the same forming a chamber between the upper ends of said parts, an internal valve within said chamber having a lower portion received in an aperture of the nipple and having shoulders contacting with the revoluble member and means for guiding the said internal valve so that the same is raised and lowered by the turning movement of the revoluble member controlling the supply of gas.

12. In a gas-regulating Bunsen burner the combination with the nipple, of a revoluble member surrounding and extending beyond the upper end thereof and having a central hole and forming an internal chamber, of a valve comprising a body portion, shoulders, a stem, conical head and upper end, a helical spring in said chamber around said valve, means for moving the valve axially of the burner and means for preventing the valve turning with such movement.

811,990. **VACUUM-BREAKER FOR CONDENSERS.** BRONSON C. WOODFORD, New York, N. Y., assignor to International Steam Pump Company, New York, N. Y., a Corporation of New Jersey. Filed Feb. 8, 1905. Serial No. 244,712.



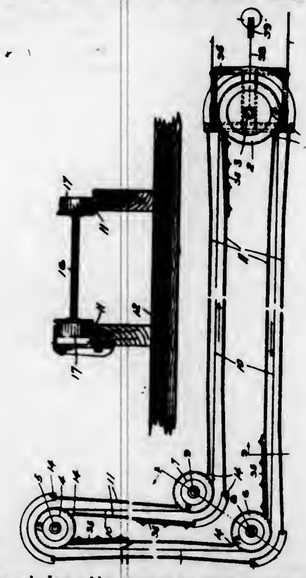
Claim.—1. The combination with a condenser, of a vacuum-breaker having an air-inlet valve exposed to atmospheric pressure on its outer side, a valve-actuating piston, a control-valve and passages for varying the pressure on said piston to open and close the air-inlet valve, and a float and connections for actuating said control-valve to secure the opening of the air-inlet valve when the liquid in the condenser reaches a certain level.

2. The combination with a condenser, of a vacuum-breaker having the inlet-valve exposed to atmospheric pressure on its outer side, a piston connected to said valve and exposed to atmospheric pressure tending to open the valve, a control-valve and passages for connecting the opposite side of the piston with the atmosphere or condensing chamber, and a float and connections for actuating said control-valve.

3. In a condenser vacuum-breaker, the combination with the air-inlet valve *b*, of piston *c* connected to the valve *b*, said valve and piston being exposed to atmospheric pressure on their adjacent sides, pressure-chamber 19 on the opposite side of said piston, passages for connecting said chamber 19 with the atmosphere or the condenser, and a float-actuated control-valve *a* controlling said passages, substantially as described.

4. In a condenser vacuum-breaker, the combination with the air-inlet valve *b*, of piston *c* connected to the valve *b*, said valve and piston being exposed to atmospheric pressure on their adjacent sides, pressure-chamber 19 on the opposite side of said piston, passages 16, 17, 18 for connecting said pressure-chamber with the atmosphere or the condenser, control-valve *a* controlling said passages, float F, and link 15 connecting said float to control-valve *a* for actuating said control-valve.

811,991. **CABLE CONVEYER.** ALFRED M. ACKLIN, Pittsburg, Pa., assignor to Heyl & Patterson, Inc., Pittsburg, Pa., a Corporation of Pennsylvania. Filed Nov. 23, 1904. Serial No. 234,080.



Claim.—1. In a cable conveyer, the combination of two or more sheaves, an endless cable engaging same, a truck or carriage, a track for same, and an intermediate flexible connection between said truck and cable adapted when connected to the cable to swing into a position at right angles, or approximately, to the axes of said sheaves.

2. In a cable conveyer, the combination of two or more sheaves, an endless cable engaging same, a truck or carriage, a track for same, and an intermediate hinged connection between said truck and cable adapted when connected to the cable to swing into a position at right angles, or approximately, to the axes of said sheaves.

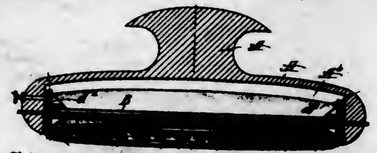
3. In a cable conveyer, the combination of two or more sheaves, an endless cable engaging same, a truck or carriage, a track for same, and a swinging clamp between said truck and cable adapted when connected to the cable to swing into a position at right angles, or approximately, to the axes of said sheaves.

4. In a cable conveyer, the combination of two or more sheaves, an endless cable engaging same, a truck or carriage, a track for same, a bracket extending down from said truck, and a swinging clamp connected to said bracket and adapted to engage said cable and when connected to the cable to swing into a position at right angles, or approximately, to the axes of said sheaves.

5. In a cable conveyer, the combination of two or more sheaves, an endless cable engaging same, a truck or carriage, a track for same, a bracket extending down from said truck having bearings therein, a clamp connected to said cable, said clamp having a bearing therein, and a pin passing through said bearings in said bracket and clamp, said clamp when connected to the cable being adapted to swing into a position at right angles, or approximately, to the axes of said sheaves.

6. In a cable conveyer, the combination of two or more sheaves, an endless cable engaging same, a truck or carriage, a track for same, the upper faces of said sheaves forming a support for said truck in passing over same, and an intermediate flexible connection between said truck and cable.

811,992. **MANICURING APPLIANCE.** ANNA A. ARGUS and DOROTHY B. CAMERON, New York, N. Y. Filed July 1, 1905. Serial No. 267,997.



Claim.—1. A manicuring appliance comprising a shell or casing having end walls, a spindle rotatably supported between said walls and having recessed heads thereon, and a plurality of pads adapted to engage the recesses of said heads.

2. A manicuring appliance comprising a frame or body having bearings, a spindle rotatably supported between said bearings, heads or flanges on said spindle said heads or flanges having spaced recesses upon their inner faces, a plurality of pads having supporting-ribs therein, and arranged to be sprung into corresponding recesses of said heads or flanges.

3. A manicuring appliance, comprising a frame or body having bearings thereon, a spindle rotatably disposed between said bearings, a pair of collars having flattened peripheral faces secured to said spindle, flanged disks surrounding said collars to form recesses therewith, and a pad engaging two of the corresponding recesses.

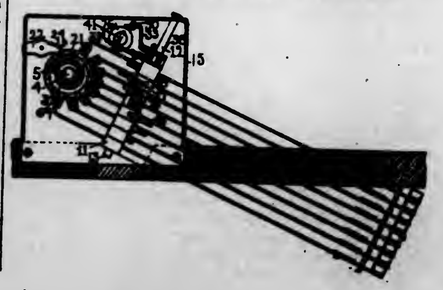
4. A manicuring appliance, comprising a frame or body having bearings, a spindle having recessed heads thereon, a pad having a longitudinal supporting-rib arranged to engage the recesses in said heads, and locking means for fixing the rotative adjustment of the spindle in any desired relation.

5. A manicuring appliance, comprising a frame or body, a spindle rotatably supported in said frame or body and having recessed heads thereon, locking means for holding said spindle in any desired relation, a supporting-rib of a length greater than the distance between the walls of corresponding recesses, and engaging such recesses and a pad including a wrapper and a packing material therein surrounding said supporting-rib.

6. As an article of manufacture, a manicuring-pad having an outer tube or wrapper of flexible material, a stiffening-rib therein, a packing material between said stiffening-rib and wrapper, the rib and wrapper being so arranged as to leave a longitudinal recess throughout the pad.

7. A manicuring appliance, comprising a shell or casing having side and end walls, a spindle rotatably journaled between said end walls, collars having flattened faces upon said spindle, flanged disks surrounding said collars so as to form heads or flanges having recesses, locking means for holding said heads in any position of rotative adjustment, and pads having an outer tube or wrapper of flexible material, a stiffening-rib therein and a supporting-rib adapted to engage the recesses of said heads or flanges, said supporting-rib being adapted to spring into bowed relation between the corresponding recesses of said heads or flanges.

811,993. **MUSIC-LEAF TURNER.** JOSEPH BAHL and JOSEPH C. BAHL, Chicago, Ill. Filed Mar. 24, 1905. Serial No. 251,260.



Claim.—1. In a music-leaf turner, in combination, a series of

means for vibrating said members, and contact means operated by

carrier, adjustable circuit-controlling devices carried thereby, means

tending to vibrate said fingers toward and away from said stops in

Claim.—1. In a music-leaf turner, in combination, a series of independently-swinging arms having means to engage the leaves, and an escapement mechanism comprising a shaft having a series of hinged teeth arranged to engage said arms respectively and to release the same by rotation of the shaft.

2. In a music-leaf turner, in combination, a series of independently-swinging arms having means to engage the leaves, and an escapement mechanism comprising a shaft having thereon a series of hinged teeth projecting from the shaft in different directions and engageable with the arms, and means to turn the shaft intermittently, to release the arms successively.

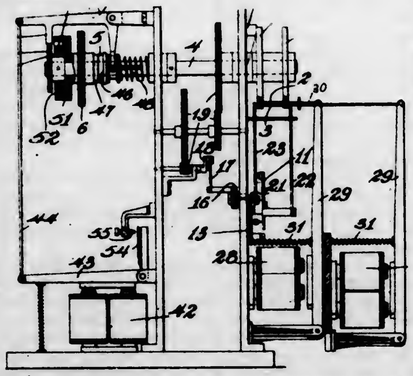
3. In a music-leaf turner, in combination, a series of swinging leaf-carrying arms, and an escapement mechanism comprising a shaft having thereon a ratchet and a series of teeth engaging the arms respectively, and a manually-operated pawl engageable with the ratchet to turn the shaft.

4. In a music-leaf turner, in combination, a series of swinging leaf-carrying arms, an escapement mechanism having a shaft provided with teeth engaging the arms, and pneumatically-actuated means to turn the shaft intermittently, to release the arms successively.

5. The combination with a music-board having a reversible section, of a music-leaf turner on the board, and a music-holding clamp on said reversible section, arranged to hold music-sheets at the fold when they are engaged by the turner.

6. The combination with a music-board having a slot therein, of a music-leaf turner having a series of arms which may be advanced or retracted through the slot, and a flap arranged to cover the slot when the arms are retracted.

811,994. **TELEGRAPH-TRANSMITTER.** JOHN C. BARCLAY, New York, N. Y., assignor to Western Union Telegraph Company, New York, N. Y., a Corporation of New York. Filed Feb. 27, 1905. Serial No. 247,462.



Claim—1. In a telegraph-transmitter, the combination with a movable carrier, adjustable circuit-controlling devices carried thereby, and means for adjusting said devices variably according to the character to be transmitted, of contact mechanism comprising controlling members adapted to be vibrated but arranged to be controlled in such vibration by said circuit-controlling devices, driving means automatically operated adapted to vibrate said members, and contact means operated by the vibration of said members.

2. In a telegraph-transmitter, the combination with a movable carrier, adjustable circuit-controlling devices carried thereby, and a keyboard and means operated thereby for adjusting said devices variably according to the character to be transmitted, of contact mechanism comprising controlling members adapted to be vibrated but arranged to be controlled in such vibration by said circuit-controlling devices, driving means automatically operated adapted to vibrate said members, and contact means operated by the vibration of said members.

3. In a telegraph-transmitter, the combination with a movable carrier, adjustable circuit-controlling devices carried thereby, magnets and means operated thereby for adjusting said devices, and selecting means controlling said magnets, of contact mechanism comprising controlling members adapted to be vibrated but arranged to be controlled in such vibration by said circuit-controlling devices, means for vibrating said members, and contact means operated by the vibration of said members.

4. In a telegraph-transmitter, the combination with a movable carrier, adjustable circuit-controlling devices carried thereby, magnets and means operated thereby for adjusting said devices, and a keyboard comprising selecting means controlling said magnets, of contact mechanism comprising controlling members adapted to be vibrated but arranged to be controlled in such vibration by said circuit-controlling devices, means for vibrating said members, and contact means operated by the vibration of said members.

5. In a telegraph-transmitter, the combination with a movable carrier, adjustable circuit-controlling devices carried thereby, and means for adjusting said devices variably according to the character to be transmitted, of contact mechanism comprising controlling members adapted to be vibrated but arranged to be controlled in such vibration by said circuit-controlling devices, driving means automatically operated adapted to vibrate said members, contact means operated by the vibration of said members, and means for arresting said carrier during the adjustment of said circuit-controlling devices.

6. In a telegraph-transmitter, the combination with a movable carrier, adjustable circuit-controlling devices carried thereby, and a keyboard and means operated thereby for adjusting said devices variably according to the character to be transmitted, of contact mechanism comprising controlling members adapted to be vibrated but arranged to be controlled in such vibration by said circuit-controlling devices, driving means automatically operated adapted to vibrate said members, contact means operated by the vibration of said members, and means for arresting said carrier during the adjustment of said circuit-controlling devices.

7. In a telegraph-transmitter, the combination with a movable carrier, adjustable circuit-controlling devices carried thereby, magnets and means operated thereby for adjusting said devices, and selecting means controlling said magnets, of contact mechanism comprising controlling members adapted to be vibrated but arranged to be controlled in such vibration by said circuit-controlling devices, means for vibrating said members, contact means operated by the vibration of said members, and means for arresting said carrier during the adjustment of said circuit-controlling devices.

8. In a telegraph-transmitter, the combination with a movable carrier, adjustable circuit-controlling devices carried thereby, magnets and means operated thereby for adjusting said devices, and a keyboard comprising selecting means controlling said magnets, of contact mechanism comprising controlling members adapted to be vibrated but arranged to be controlled in such vibration by said circuit-controlling devices, means for vibrating said members, contact means operated by the vibration of said members, and means for arresting said carrier during the adjustment of said circuit-controlling devices.

9. In a telegraph-transmitter, the combination with a movable carrier, adjustable circuit-controlling devices carried thereby, operating mechanism for said carrier comprising means for driving said carrier intermittently, and means for adjusting said circuit-controlling devices arranged to adjust the same while the carrier is stationary, of contact mechanism comprising controlling members adapted to be vibrated but arranged to be controlled in such vibration by said circuit-controlling devices, means other than said circuit-controlling devices for vibrating said members, and contact means operated by the vibration of said members.

10. In a telegraph-transmitter, the combination with a movable carrier, adjustable circuit-controlling devices carried thereby, means comprising a clutch for driving said carrier, and a magnet and means operated thereby for opening said clutch, magnets and means operated thereby for adjusting said circuit-controlling devices, selecting means controlling said adjusting-magnets, and means operated by said clutch-magnet likewise controlling said adjusting-magnets and arranged to prevent the operation thereof until the clutch is open, of contact mechanism controlled by said circuit-controlling devices.

11. In a telegraph-transmitter, the combination with a movable carrier, adjustable circuit-controlling devices carried thereby, means comprising a clutch for driving said carrier, a magnet and means operated thereby for opening said clutch, adjusting-magnets and means operated thereby for adjusting said circuit-controlling devices, selecting means controlling said adjusting-magnets, and a relay controlled by said clutch-magnet having contact devices arranged to prevent the operation of said adjusting-magnets until after the clutch has opened and to cause said magnets to disengage their adjusting means from said circuit-controlling devices prior to the closing of said clutch, of contact mechanism controlled by said circuit-controlling devices.

12. In a telegraph-transmitter, the combination with a movable carrier, adjustable circuit-controlling devices carried thereby, means comprising a clutch for driving said carrier, a magnet and means operated thereby for opening said clutch, adjusting-magnets and means operated thereby for adjusting said circuit-controlling devices, selecting means controlling said adjusting-magnets, and a relay controlled by said clutch-magnet and having contact means arranged to close circuit through the selected adjusting-magnets upon the commencement of movement of its armature in one direction and to break said circuit prior to the completion of such movement, of contact mechanism controlled by said circuit-controlling devices.

13. In a telegraph-transmitter, the combination of a movable carrier, adjustable circuit-controlling devices carried thereby, magnets for adjusting said circuit-controlling devices, and a keyboard and means operated thereby controlling the circuits of said magnets.

14. In a telegraph-transmitter, the combination of a movable carrier, adjustable circuit-controlling devices carried thereby, magnets for adjusting said circuit-controlling devices, and a keyboard comprising selecting-contacts each corresponding to and controlling a circuit through one of said adjusting-magnets, and also comprising selecting means, differently operated by the different keys of said keyboard, operating said selecting-contacts.

15. In a telegraph-transmitter, the combination of a movable carrier, adjustable circuit-controlling devices carried thereby, magnets for adjusting said circuit-controlling devices, and a keyboard comprising selecting mechanism including contacts controlling the circuits of the several adjusting-magnets and a master-contact, closed by each key after the closing of the selecting-contacts operated thereby, said master-contact controlling the circuits of all said adjusting-magnets.

16. In a telegraph-transmitter, the combination of a movable carrier, adjustable circuit-controlling devices carried thereby, magnets for adjusting said circuit-controlling devices, a stop-magnet arranged when operated to arrest the movement of said carrier, a keyboard comprising selecting mechanism including contacts controlling the circuits of the several adjusting-magnets and a master-contact, closed by each key after the closing of the selecting-contacts operated thereby, said master-contact controlling said stop-magnet, and means operated by said stop-magnet controlling the circuits of all of said adjusting-magnets.

17. In a telegraph-transmitter, the combination of a movable carrier, adjustable circuit-controlling devices carried thereby, magnets for adjusting said circuit-controlling devices, a stop-magnet arranged when operated to arrest the movement of said carrier, a keyboard comprising selecting mechanism including contacts controlling the circuits of the several adjusting-magnets and a master-contact, closed by each key after the closing of the selecting-contacts operated thereby, said master-contact controlling said stop-magnet, and a relay operated by said stop-magnet having contact means arranged to close circuit through the selected adjusting-magnets upon the commencement of movement of its armature and to break such circuit prior to the completion of such movement.

18. In a telegraph-transmitter, the combination of a movable carrier, longitudinally-movable stops carried thereby, means for adjusting said stops, contact mechanism comprising controlling means having springs tending to press said controlling means against said stops, and means other than said stops for vibrating said controlling means.

19. In a telegraph-transmitter, the combination of a movable carrier, longitudinally-movable stops carried thereby, operating mechanism for said carrier comprising means for driving said carrier intermittently, means for adjusting said stops arranged to operate while said carrier is stationary, contact mechanism comprising controlling means having springs tending to press said controlling means against said stops, and means other than said stops for vibrating said controlling means.

20. In a telegraph-transmitter, the combination of a movable carrier, longitudinally-movable stops carried thereby, operating mechanism for said carrier comprising means for driving said carrier intermittently, means for adjusting said stops arranged to operate while said carrier is stationary, and contact mechanism comprising controlling-fingers spring-pressed toward said stops, means tending to vibrate said fingers toward and away from said stops in synchronism with the passage of the stops, and contact means operated by the vibration of said fingers.

21. In a telegraph-transmitter, the combination of a driving-shaft, a drum thereon, longitudinally-movable stops carried thereby, operating mechanism for said carrier comprising means for driving said shaft intermittently, means for adjusting said stops arranged to operate while the shaft is stationary, and contact mechanism comprising controlling-fingers spring-pressed toward said stops, means tending to vibrate said fingers toward and away from said stops in synchronism with the passage of the stops, and contact means operated by the vibration of said fingers.

22. In a telegraph-transmitter, the combination of a driving-shaft, a drum thereon, longitudinally-movable stops carried thereby, means for adjusting said stops, and contact mechanism comprising controlling-fingers spring-pressed toward said stops, means tending to vibrate said fingers toward and away from said stops in synchronism with the passage of the stops, and contact means operated by the vibration of said fingers.

23. In a telegraph-transmitter, the combination with a driving-shaft, a drum thereon, longitudinally-movable stops carried thereby, means for adjusting said stops, and contact mechanism comprising controlling-fingers spring-pressed toward said stops, one of said fingers arranged to be arrested in its movement by the opposite stop if said stop be in normal position, but to be free to move in case said stop has been adjusted, the other finger arranged to be unimpeded in its movement by said stops when the latter are in normal position, but to be arrested in its movement by the stop opposite it if such stop has been moved to its adjusted position, and contact means operated by the vibration of said fingers.

24. In a telegraph-transmitter, the combination with a moving carrier, circuit-controlling means carried thereby, and a clutch for driving said carrier, of a locking-wheel likewise driven by said clutch, means for opening said clutch and engaging said locking-wheel to lock the carrier, and a friction-drag tending to rotate the carrier while so locked.

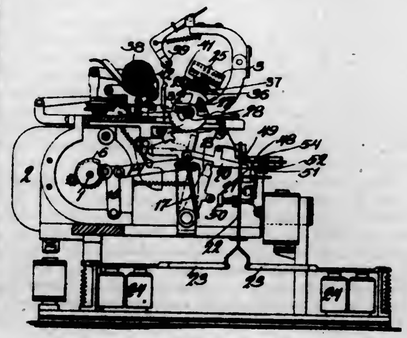
25. In a telegraph-transmitter, the combination of a rotatably-mounted drum, longitudinally-movable stops carried thereby, radially-arranged adjusting-arms, push-pins operated thereby for moving said stops longitudinally, means for operating said arms, means guiding said push-pins, and means for resetting the stops.

26. In a telegraph-transmitter, the combination of a rotatably-mounted drum, longitudinally-movable stops carried thereby, adjusting-magnets arranged circularly about said drum, armature-levers therefor provided with means for moving said stops longitudinally, means for operating said arms, means guiding said push-pins, and means for resetting the stops.

27. In a telegraph-transmitter, the combination of a movably-mounted carrier, longitudinally-movable stops carried thereby, adjusting-magnets, armature-levers therefor provided with means for moving said stops longitudinally, means for resetting said stops, means for arresting the movement of the carrier, and a relay operated by said arresting means and having contact means controlling the circuits of said adjusting-magnets and arranged to complete such circuits, as to said contact means, upon the beginning of the movement of the armature of said relay, and to break such circuits prior to the completion of the movement of said armature.

28. In a telegraph-transmitter, the combination with a keyboard, transmitting-contact mechanism, and operating mechanism controlled by said keyboard and controlling the operation of said transmitting-contact mechanism, of a relay controlled by said transmitting-contact mechanism and provided with contact means arranged to repeat the signals of said contact mechanism into a line-circuit, said relay provided with means for giving bias.

811,995. **PRINTING MECHANISM.** JOHN C. BERCLAY, New York, N. Y., assignor to Western Union Telegraph Company, New York, N. Y., a Corporation of New York. Filed Mar. 24, 1905. Serial No. 251,804.



Claim.—1. The combination with printing mechanism comprising means for printing at will any one of a plurality of characters, operating means therefor comprising a driver, a plurality of engaging means, and means for moving any one of said engaging means into position for engagement with said driver, of locking means for said engaging means which holds any one of the latter which has been operated, in position for engagement until engaged with said driver.

2. The combination with printing mechanism comprising selecting means, a driver therefor, and engaging means for operatively connecting said selecting means and driver, of operating means for said engaging means, and locking means for holding said engaging means in position for engagement until such engagement is accomplished.

3. The combination with printing mechanism comprising selecting means, a driver therefor, and engaging means for operatively connecting said selecting means and driver, of operating means for said engaging means, locking means for holding said engaging means in position for engagement until such engagement is accomplished, and means for releasing the locking means.

4. The combination with printing mechanism comprising selecting means, a driver therefor, and engaging means connected to said selecting means and normally out of, but arranged to be drawn into, position for engagement with said driver, of operating means for said engaging means, and locking means for holding said engaging means in position for engagement with the driver until such engagement is accomplished.

5. The combination with printing mechanism comprising selecting means, a driver therefor, and engaging means connected to said selecting means and normally out of, but arranged to be drawn into, position for engagement with said driver, of operating means for said engaging means, locking means for holding said engaging means in position for engagement with the driver until such engagement is accomplished, and means for releasing the locking means.

6. The combination with printing mechanism comprising tumblers, gear-sectors for rotating the same, a driver, and pawls carried by said gear-sectors and normally out of engagement with said driver, but arranged to be drawn into position for such engagement, of operating means for said pawls, and locking means for holding each pawl, when the latter is moved into position for engagement with the driver, in such position until engaged by the driver.

7. The combination with printing mechanism comprising tumblers, gear-sectors for rotating the same, a driver, and pawls carried by said gear-sectors and normally out of engagement with said driver, but arranged to be drawn into position for such engagement, of operating means for said pawls, locking means for holding each pawl, when the latter is moved into position for engagement with the driver, in such position until engaged by the driver, and means for releasing said locking means.

8. The combination with printing mechanism comprising tumblers, gear-sectors for rotating the same, a driver, and pawls carried by said gear-sectors and normally out of engagement with said driver, but arranged to be drawn into position for such engagement, of operating means for said pawls, locking means for holding each pawl, when the latter is moved into position for engagement with the driver, in such position until engaged by the driver, and means operated by said driver for releasing said locking means.

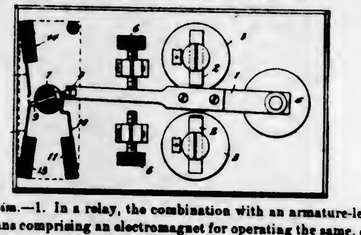
9. The combination with printing mechanism comprising tumblers, gear-sectors for rotating the same, a driver, and pawls carried by said gear-sectors and normally out of engagement with said driver, but arranged to be drawn into position for such engagement, operating means for said pawls, latches for the said pawls adapted to engage and hold each pawl when the latter is moved into position for engagement with the driver, and means for releasing said latches.

10. The combination with printing mechanism comprising tumblers, gear-sectors for rotating the same, a driver, and pawls carried by said gear-sectors and normally out of engagement with said driver, but arranged to be drawn into position for such engagement, operating means for said pawls, latches for the said pawls adapted to engage and hold each pawl when the latter is moved into position for engagement with the driver, and means operated by the driver for releasing said latches.

11. The combination with printing mechanism comprising tumblers, gear-sectors for rotating the same, a driver, and pawls carried by said gear-sectors and normally out of engagement with said driver, but arranged to be drawn into position for such engagement, operating means for said pawls, latches for the said pawls adapted to engage and hold each pawl when the latter is moved into position for engagement with the driver, and a universal release-bar operated by said driver as it moves forward, and arranged when operated to engage and release whichever of said latches has been operated.

12. The combination with printing mechanism comprising tumblers, gear-sectors for rotating the same, a driver, and pawls carried by said gear-sectors and normally out of engagement with said driver, but arranged to be drawn into position for such engagement, of rods for operating said pawls, spring-pressed locking-bolts therefor each adapted to engage a lug on the corresponding rod when said rod is depressed, and means operated by the driver for releasing said rods.

811,996. **RELAY.** JOHN C. BARCLAY, New York, N. Y., assignor to Western Union Telegraph Company, New York, N. Y., a Corporation of New York. Filed July 11, 1905. Serial No. 269,164.

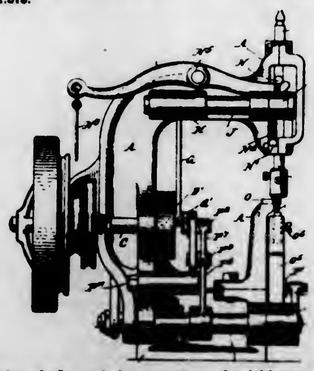


Claim.—1. In a relay, the combination with an armature-lever and means comprising an electromagnet for operating the same, of a vibrating member separately mounted but having a driving connection with said armature-lever, and a plurality of projecting contact-pieces carried thereby and insulated from each other, and other contact devices against which said contact-pieces of the vibrating member play as the latter vibrates, thereby making and breaking contact.

2. In a relay, the combination with an armature-lever and means comprising an electromagnet for operating the same, of a vibrating member separately mounted but having a driving connection with said armature-lever, a plurality of projecting contact-pieces carried thereby and insulated from each other, contact devices against which said contact-pieces of the vibrating member play as the latter vibrates, thereby making and breaking contact, and other contact-pieces in permanent electrical connection with said vibrating contact-pieces, arranged to make connection therewith while permitting motion thereof.

3. In a relay, the combination with an armature-lever and means comprising an electromagnet for operating the same, of a rocker of insulating material mounted to oscillate and having a driving connection with said armature-lever, contact-pins carried thereby extending through said rocker, and each projecting therefrom at one end, contact-brushes permanently in contact with said pins and serving to convey electric current thereto, and other contact-brushes arranged in proximity to the said projecting ends of said pins and arranged to make and break contact therewith as the rocker oscillates.

811,997. **STITCH-SEPARATOR AND PRICKING-UP MACHINE.** THOMAS D. BARRY, Brockton, Mass. Filed May 23, 1905. Serial No. 261,573.



Claim.—1. In a stitch-separating and pricking-up machine, a work-support, a stitch-separator adapted to enter between the stitches and indent the same, mechanism for operating said stitch-separator, means for varying the indentation of said stitch-separator, a device engaging the bottom of the sole for moving the shoe after each indentation, independently of the movement of the stitch-separator, and mechanism for operating said feed device to move the work between the stitch-indenting operations.

2. In a stitch-separating and pricking-up machine, a work-support, a yielding stitch separator adapted to enter between the stitches and indent the same, mechanism for operating said stitch-separator, means for varying the indentation of said stitch-separator, a device engaging the bottom of the sole for moving the shoe after each indentation independently of the movement of the stitch-separator, and mechanism for operating said feed device to move the work between the stitch-indenting operations.

3. In a stitch-separating and pricking-up machine, a work-support, a stitch-separator adapted to enter between the stitches to indent the same, mechanism for operating the stitch-separator, means for varying the indentation of said stitch-separator, a presser-foot for the work, a device engaging the bottom of the sole for moving the shoe after each indentation independently of the movement of the stitch-separator, and mechanism for operating said feed device to move the work between the stitch-indenting operations.

4. In a stitch-separating and pricking-up machine, a work-support, a stitch-separator operating to enter between the stitches to indent the same, mechanism for actuating said stitch-separator, means for varying the indentation of said stitch-separator, a feed device for engaging the bottom of the sole to move the shoe after each indentation independently of the movement of the stitch-separator, a carrier for said feed device, means for adjusting said feed device on said carrier to accommodate the stitches, and mechanism for operating said feed device to move the work between the stitch-indenting operations.

5. In a stitch-separating and pricking-up machine, a work-support, a stitch-separator operating to enter between the stitches to indent the same, mechanism for actuating said stitch-separator, means for varying the indentation of said stitch-separator, an awl-feed operating to engage the sole of the shoe to move the same after each indentation independently of the movement of the stitch-separator, a carrier for said awl-feed, means for adjusting said awl-feed on said carrier to accommodate the stitches, and mechanism for actuating said awl-feed to move the work between the stitch-indenting operations.

6. In a stitch-separating and pricking-up machine, a work-support, a stitch-separator operating to enter between the stitches to indent the same, mechanism for actuating said stitch-separator, means for varying the indentation of said stitch-separator, an awl-feed operating to engage the bottom of the sole to move the shoe after each indentation independently of the movement of the stitch-separator, an oscillating arm on which said awl-feed is mounted, means for adjusting said awl-feed on said arm to accommodate the stitches, and means for actuating said arm to move the work between the stitch-indenting operations.

811,998. **AMUSEMENT DEVICE.** EDWARD S. BENEDICT, New York, N. Y. Filed Aug. 25, 1905. Serial No. 275,706.

Claim.—1 The combination with a movable vehicle, of means for directing a stream of water into the path of travel of the vehicle, and means controlled by the movement of the vehicle for starting and stopping the flow of water.

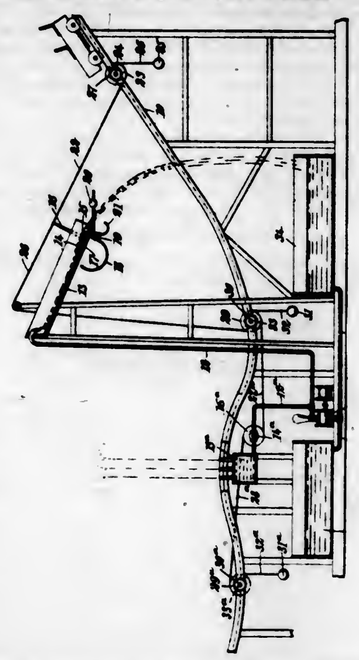
2. The combination with a track for vehicles, of means for directing a stream of water into the path of travel of the vehicle on the track, and means for automatically stopping the stream when the vehicle approaches it

3. The combination of means for directing a stream of water into the path of travel of a vehicle, means for automatically stopping the stream when the vehicle approaches it, and means for starting the flow of water after the vehicle has passed through the path thereof.

4. The combination of means for directing a stream of water into the path of a vehicle, a shaft located adjacent to the path and having means adapted to be engaged by a vehicle for rotating the shaft, means for stopping said stream of water, and means for connecting said shaft and said last-named means.

5. A track for vehicles having a shaft located adjacent thereto, means on the shaft adapted to be engaged and turned by a vehicle on the track, a drum on said shaft, a flexible member adapted to be wound on the drum, a water-controlled device connected with said flexible member, and means for directing a flow of water against said track.

6. The combination with means for directing a stream of water in a certain path, means for controlling the flow of water in said stream, a flexible member connected with said last-named means, a drum upon which said member is adapted to be wound, a shaft connected with the drum, and a gear mounted on said shaft.



7. The combination with means for directing a stream of water in a certain path, means for controlling said stream of water, a pair of flexible members connected with said last-named means, a pair of drums upon which said members are adapted to be wound, and a gear connected with each of said drums whereby the rotation of the gears will cause the drums to be rotated to wind up the flexible members thereon.

8. The combination of a pump, a device for directing a stream of water, means connected with the pump for supplying said device with water, means for controlling the flow of water through said device, a pair of flexible connections extending from said last-named means in two directions whereby a pull on one of said members will stop the flow of water and a pull on the other will start it, a pair of drums upon which said members are adapted to be wound, means rigidly connected with said drums for causing them to be rotated to wind up the flexible members thereon in succession, and counterweights for normally unwinding the flexible members from said drums.

9. The combination of a pump, a fountain, an inclined trough, means connected with the pump for supplying the fountain and trough with water, means for controlling the flow of water through said fountain, means for controlling the flow of water through said trough, each of said two last-named means comprising a drum, a flexible connection adapted to be wound on the drum and connected with the means for supplying water, and a pinion on each drum, and a vehicle adapted to move adjacent to said fountain and trough and having a rack for engaging said pinion and operating the same.

10. The combination of a railway, a fountain located adjacent thereto, and adapted to force a stream of water across the path of a vehicle on the railway, an inclined trough located above the railway, means for supplying water to the fountain and trough, means for controlling said supplying means, and means operable by the passage of a vehicle for operating said controlling means.

11. A water-trough having an open end, an opening in its bottom, and means for alternately closing the end and the opening.

12. An inclined water-trough having means at its lower end for directing water in a stream to represent a natural waterfall, an outlet above said means, and means for alternately rendering said first-named means inoperative and closing the outlet.

13. The combination of a trough having two discharge-outlets,

means for alternately opening said outlets, and a movable trough located below the first-named trough and adapted to intercept water discharged from the two outlets.

tongs attached to the pipe nearer to said table and fixed upon said table.

2. The combination with a casing a valve mounted on a movable valve-stem therein, an arm for lifting the valve-stem, said arm being

covered adjacent the edge of the body portion, tongues cut from the blank excepting along certain lines which are scored, lips surrounded

means for alternately opening said outlets, and a movable trough located below the first-named trough and adapted to intercept water discharged from the two outlets.

14. The combination of a trough having two discharge-outlets, means for alternately opening said outlets, and a movable trough located below the first-named trough and adapted to intercept water discharged from the two outlets; said trough having a portion located below each outlet, and a counterweight for moving one of said portions out of operative position.

15. An artificial waterfall, comprising an inclined trough having an open lower end and an opening in its bottom above said end, and a pivoted trough located below said opening in the bottom of the main trough, said trough being provided with a lip adapted to project into a position below the open end of the main trough.

811,999. **SAFETY-RAZOR.** PETER A. BENNY, Boston, Mass. Filed June 29, 1905. Serial No. 268,169.

Claim.—1. A pocket-razor comprising a handle, a stud normally depressed within said handle, means for extending said stud from said handle, and means for supporting a blade on said stud.

2. A pocket-razor having a handle with an opening in the extremity thereof, a depressible stud mounted in said opening, a member engaging said stud and affording means for projecting the same from said handle, a blade, and means for supporting said blade on said stud.

3. A pocket-razor comprising a handle having an opening in the extremity thereof, a threaded stud mounted in said opening, a spring constraining said stud inwardly, a cap rotatably mounted on the extremity of said handle and engaging the threads of said stud, a guard-plate detachably connected to the said stud and a blade carried by said guard-plate.

4. A pocket safety-razor comprising a handle having an angular opening in the extremity thereof, a stud having an angular neck mounted in said opening and having a threaded shank projecting therebeyond, a spring under the head of said stud and tending to force the same inwardly, a cap rotatably mounted on the extremity of said handle and engaging the threads of said stud, and a guard-plate having a threaded opening adapted to receive the extremity of said stud and adapted to carry the blade.

812,000. **ROTARY FOR OIL-WELLS.** HORACE D. BERNARD, Beaumont, Tex. Filed Sept. 16, 1905. Serial No. 278,985.

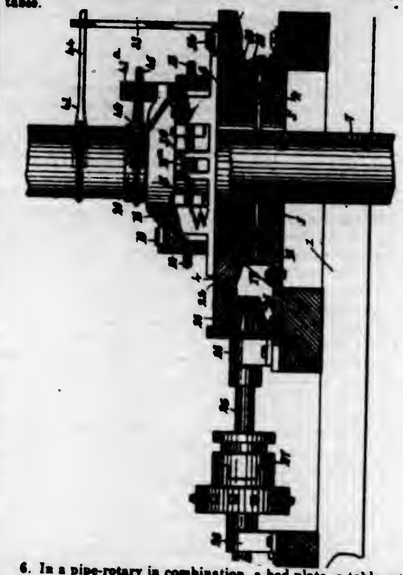
Claim.—1. In a pipe-rotary in combination, a rotatable table, means for fixing the same against rotation, a rotatable ring mounted on said table, a bracket carried by said ring and adapted to engage pipe-tongs attached to the pipe, and means for rotating said ring.

2. In a pipe-rotary in combination, a rotatable table, a rotatable ring carried thereby, means for locking said ring and said table together, means for locking said table against rotation, and a bracket carried by said ring and adapted to engage pipe-tongs attached to the pipe.

3. In a rotary in combination, a rotatable table having an opening through which a pipe may pass upwardly, a rotatable ring mounted on said table, a bracket carried by said ring, pipe-tongs adapted to be engaged by said bracket when attached to said pipe, a second pipe-tongs adapted to be attached to said pipe, and means for securing said second pipe-tongs against rotation.

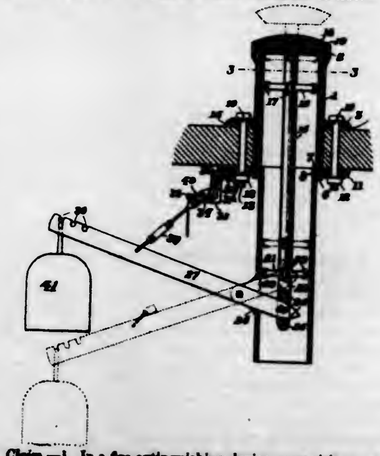
4. In a rotary in combination, a rotatable table, means for locking the same against rotation, said table having a central opening through which a pipe may pass upwardly, a rotatable ring mounted on said table, means for locking said ring to said table, said ring having lugs upon the upper face thereof, and a bracket attached to said lugs and projecting upwardly from said ring, said bracket presenting notches on the opposite sides thereof adapted to engage the pipe-tongs.

5. In a rotary in combination, a bed-plate, a table rotatably mounted thereupon, means for locking said table against rotation on said bed-plate, a ring rotatably mounted on the edge of said table, said table and said ring having openings formed in the joint therebetween, and removable pins adapted to occupy said openings to lock said ring to said table, a member carried by said ring and adapted to engage pipe-tongs attached to a pipe passing up through said table, and a second member projecting upwardly to receive a second pipe-tongs attached to the pipe nearer to said table and fixed upon said table.



6. In a pipe-rotary in combination, a bed-plate, a table rotatably mounted thereupon, said table and said bed-plate having alining openings through which a pipe may pass upwardly, said table having a circumferential groove, clips projecting into said groove and securing said table to said bed-plate, means for locking said table against rotation, a ring rotatably mounted on said table, a bracket carried by said ring and adapted to engage a pipe-tongs applied to said pipe, and a fixed member projecting upwardly from said table and adapted to engage a second pipe-tongs attached to said pipe nearer to said table.

812,001. **FIRE-EXTINGUISHING DEVICE.** WILLIAM C. BILS, New York, N. Y. Filed Mar. 26, 1905. Serial No. 251,207.



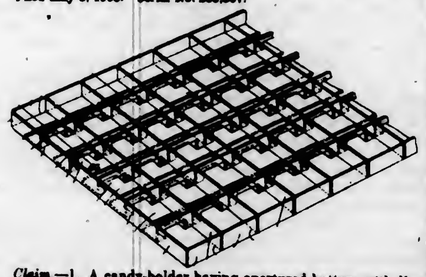
Claim.—1. In a fire-extinguishing device, comprising a casing, a valve-seat extending downwardly from the top into said casing, a valve mounted on a valve-stem, and adapted to register with the valve-seat on the top of the casing; spiders fixed to said valve-stem for guiding the valve-stem in its movements, a projection fixed to one of the spiders and extending downward in said casing, a lever operatively attached to said projection, a graduated scale of notches on the outer end of the lever for engaging a weight and a turnbuckle connection for holding the lever to the means for operating same.

2. The combination with a casing a valve mounted on a movable valve-stem therein, an arm for lifting the valve-stem, said arm being mounted on the side of said casing and the end of the arm extending into the casing, adapted to engage with rollers mounted on a projection attached to the valve-stem, and a fusible joint connecting the arm with a lock-pin in a yoke attached to a washer on the under side of the tank, and means for manually withdrawing the lock-pin from the yoke, thereby releasing the valve-operating mechanism.

3. The combination with a water-tank, a casing secured to and projecting from the bottom of said tank, a valve mounted on a movable valve-stem in said casing, a lever for lifting the valve-stem, said lever being mounted on the side of the casing, one end of said lever extending into the casing, said end being adapted to engage with rollers mounted on a projection attached to the valve-stem, a fusible joint, separable by heat, connecting the lever with a lock-pin in a yoke which is attached to a washer secured to the bottom of the tank, and means for manually withdrawing the lock-pin from the yoke thereby releasing the valve-operating mechanism.

4. The combination with a water-tank, a casing secured to the bottom of said tank, a valve mounted on an actuating valve-stem in said casing, a lever for lifting the valve-stem, said lever being mounted on the side of the casing, one end of the lever extending into the casing, said end being adapted to engage with rollers mounted on a projection attached to the valve-stem, a thermally-controlled joint connecting the lever with a locking means in a yoke attached to a washer on the bottom of the tank, and means for manually withdrawing the locking means from the yoke thereby releasing the valve-operating mechanism.

812,002. **CANDY-HOLDER.** GUSTAV A. BEHLER, Philadelphia, Pa. Filed May 3, 1905. Serial No. 258,587.



Claim.—1. A candy-holder having apertured bottom with lips integral with the bottom and extending into said apertures, integral tongues at an angle to said bottom and apertured with the apertures complemental to said lips, said tongues being complemental to the apertures of the bottom.

2. A candy-holder comprising partitions formed by intermediate portions of the blank and extending from one side of the holder to the other, integral tabs forming the sides of the holder, and tongues extending upwardly between the partitions, said tongues and the bottom of the holder being apertured, the apertures of the bottom being complementary to the tongues.

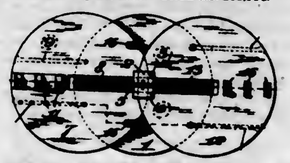
3. A candy-holder comprising partitions formed by intermediate portions of the blank and extending from one side of the holder to the other, integral tabs forming the sides of the holder, and tongues extending upwardly between the partitions, said tongues and the bottom of the holder being apertured, the apertures of the bottom being complementary to the tongue, and means integral with the bottom and surrounded by the apertures thereof.

4. A candy-holder comprising partitions formed by intermediate portions of the blank and extending from one side of the holder to the other, integral tabs forming the sides of the holder, and tongues extending upwardly between the partitions, said tongues and the bottom of the holder being apertured, the apertures of the bottom being complementary to the tongue, and means integral with the bottom and surrounded by the apertures thereof, said integral means being complementary to the apertures of the tongue.

5. A candy-holder formed from a blank and comprising in a single element, a bottom with apertures with lips, tabs extending at a right angle to the bottom, a partition between each line of apertures and apertured tongues extending at right angles to the bottom and to said partitions, the apertures of the tongues being formed by the cutting of the said lips.

6. In a blank for forming a holder for candy, a body portion, tabs extending at suitable intervals on each side thereof and being scored adjacent the edge of the body portion, tongues cut from the blank excepting along certain lines which are scored, lips surrounded by the cuts for said tongues and a plurality of scored lines extending between said tongues.

812,003. **ANCHOR FOR GUY-WIRES.** JASPER BLACKBURN, Chillicothe, Mo. Filed May 24, 1905. Serial No. 261,264.



Claim.—1. In an anchor for guy-wires, a base-plate and a pair of plates equal in diameter to the base-plate and adapted to slide in opposite directions on said base-plate, substantially as specified.

2. In an anchor for guy-wires, a base-plate, a post integral with and extending upwardly therefrom, and a plurality of plates equal in diameter to the base-plate and adapted to slide in opposite directions away from the post; substantially as specified.

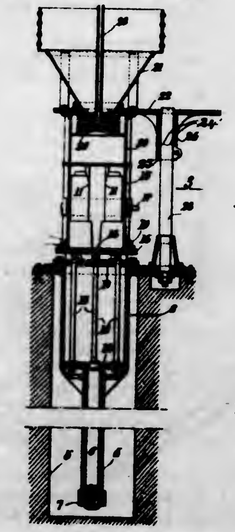
3. In an anchor for guy-wires, a base-plate, a post projecting upwardly from said base-plate, and a plurality of plates equal in diameter to the base-plate and arranged to be shifted laterally relative the base-plate and post; substantially as specified.

4. In an anchor for guy-wires, a base-plate, a post integral therewith and projecting upwardly therefrom, and a pair of plates equal in diameter to the base-plate and adapted to be shifted in opposite directions relative one another, and there being slots formed in said shifting plates through which slots passes the post carried by the base-plate; substantially as specified.

5. An anchor for guy-wires, constructed with a base-plate, a pair of plates arranged to slide upon said base-plate, there being grooves formed in the under sides of the sliding plates, and pins projecting upwardly from the base-plate into the grooves in the sliding plates; substantially as specified.

6. An anchor for guy-wires, constructed with a base-plate, a plurality of plates arranged to slide laterally upon said base-plate, a post integral with the base-plate, there being slots formed in the sliding plates through which the post projects, there being grooves formed in the under sides of the sliding plates, pins projecting upwardly from the base-plate into the grooves, and lugs formed integral with the tops of the sliding plates to be engaged by suitable separating devices; substantially as specified.

812,004. **MOLDING-MACHINE.** PHILIBERT BONVILLAIN, Paris, France. Filed Apr. 24, 1905. Serial No. 257,056.



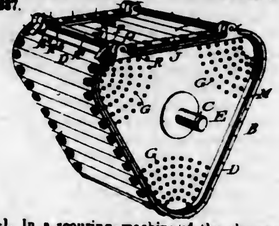
Claim.—In a molding-machine, the combination with a fixed table adapted to hold one or more similar patterns, a stripping-plate

14. An apparatus of the character described, comprising a hook-

Claim.—A jar-wrench comprising a handle formed at one end

Claim.—In a molding-machine, the combination with a fixed table adapted to hold one or more similar patterns, a stripping-plate for surrounding said patterns, vertical rods fixed to the stripping-plate and passing through the fixed table, a plate connecting the lower extremities of said vertical rods, a piston having its upper extremity fixed to said plate, a cylinder in which the piston moves, said cylinder being rigidly connected with the fixed table, a frame for surrounding the patterns and resting upon the stripping-plate, a vertical column fixed at the side of the machine, a rotatable support upon the column, a second frame of the same form as the one which surrounds the patterns, the same being fixed to the said support, a hopper surmounting the second frame, and a rammer conforming to the interior form of said frames and fitted to surround the patterns, substantially as described and for the object specified.

812,005. **MACHINE FOR SCOURING GARMENTS, FABRICS, &c.** ANDRÉ F. BORNOT, Philadelphia, Pa. Filed Jan. 9, 1904. Serial No. 188,387.



Claim.—1. In a scouring-machine of the character stated, a rumble consisting of a body, a closing-cover for the inlet thereof, braces around said body, longitudinally-extending braces on said cover, pairs of ears respectively at the pivotal and free ends of said cover, the members of each pair of ears having registering openings therein, an axial bolt passing through the ears at the pivotal end of said cover, securing-bolts passing through the ears at the free end of said cover and a tubular casing extending transversely over the cover and containing said securing-bolts.

2. In a scouring-machine of the character stated, a rumble consisting of a body, a closing-cover for the inlet thereof, braces on said body and cover respectively, ears continuous of the braces of the body, ears continuous of the braces of the cover and a fastening device in the adjacent ears of the cover and body.

3. In a scouring-machine of the character stated, a rumble consisting of a body, a closing-cover for the inlet thereof, braces on said body and cover respectively, ears continuous of the braces of the body, ears continuous of the braces of the cover, said ears having registering openings, fastening devices for the cover in said openings, and lips extending forwardly from the cover and continuous of the ears thereof and adapted to overhang the adjacent portion of the body and rest thereupon.

812,006. **APPARATUS FOR THE CONSTRUCTION OF PLASTIC WALLS.** DAVID W. BOYER, Waterloo, Iowa. Filed Aug. 12, 1905. Serial No. 273,995.

Claim.—1. An apparatus of the character described, comprising mold-sections having projections carried by their outer faces adjacent to the upper and lower edges, and having recesses in their outer faces, and stripe extending in the recesses and holding said sections in a vertical alinement.

2. An apparatus of the character described, comprising mold-sections, oppositely-arranged projections carried by the abutting ends, locking-plates having recesses to receive said projections, outwardly-extending projections carried by the upper and lower edges of said sections, and recesses in the outer side walls thereof, and a strip resting within the said recesses and holding said sections in vertical alinement.

3. An apparatus of the character described, comprising a backing, mold-sections adjacent thereto, tapering bolts securing said sections to the backing, oppositely-arranged projections carried by the abutting ends of said sections and forming tapering dovetail projections, locking-plates having dovetail recesses to receive said projections, outwardly-extending projections carried by the upper and lower edges of said sections, and having recesses in the outer side walls thereof, and a strip resting in said recesses of said projections and held therein and holding the said sections in a vertical alinement against lateral movement.

4. An apparatus of the character described, comprising a backing, mold-sections adjacent thereto, tapering bolts having a reduced screw-threaded portion passing through the backing, a nut carried thereby on the outside of the backing and the opposite end of said bolt having a reduced screw-threaded portion passing through the mold-sections, and a nut carried by said screw-threaded portion on the inside and outside of the mold-sections.

5. An apparatus of the character described, comprising a backing, mold-sections adjacent thereto, tapering bolts having a reduced screw-threaded portion passing through the backing, a nut carried thereby on the outside of the backing and the opposite end of said bolt having a reduced screw-threaded portion passing through the mold-sections, removable tapering sleeves carried by said reduced screw-threaded portion, and nuts carried thereby on the outside of the sleeve and on the inside and outside of the mold-sections.

6. An apparatus of the character described, comprising a plurality of separate mold-sections, a strip passing along the abutting edges of adjacent sections, and means for interlocking the sections with the strip.

7. An apparatus of the character described, comprising a plurality of mold-sections arranged out of line with each other, and a locking-strip spanning the junction of the said mold-sections and serving to interlock them in proper position.

8. An apparatus of the character described for forming structures with angular-arranged walls, comprising a plurality of mold-sections arranged at an angle to each other, and a locking-strip spanning the apex of the angle and extending parallel with the said sections and serving to lock them in position.

9. An apparatus of the character described for forming arch-work, comprising a plurality of mold-sections placed in arch relation, and a combined arch-shaped supporting and holding strip interlocking with said mold-sections.

10. An apparatus of the character described, comprising mold-sections having projections carried by their outer faces adjacent its upper and lower edges, and having recesses in their outer faces, and a horizontally-arranged thin strip extending in the recesses and holding said sections in a vertical alinement.

11. An apparatus of the character described, comprising mold-sections having projections carried by their outer faces adjacent their upper and lower edges, and having recesses in their outer faces, horizontally-arranged thin stripe extending in the recesses and holding said sections in a vertical alinement, projections carried by the vertical edges of the mold-sections and forming tapering dovetail projections, and a locking-plate having a dovetail recess to receive said projections and holding the ends of said sections together.

12. An apparatus of the character described, comprising a backing, mold-sections adjacent thereto, tapering bolts having a reduced screw-threaded portion passing through the backing, a nut carried thereby on the outside of the backing, and the end of said bolt having an elongated reduced screw-threaded portion passing through the mold-sections, a series of removable tapering sleeves loosely mounted on said reduced screw-threaded portion, and nuts carried thereby on the outside of the sleeve, one on each side of the mold-sections.

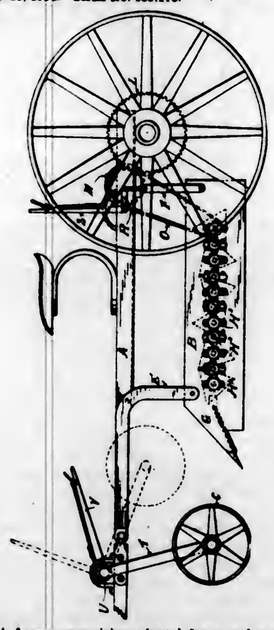
13. An apparatus of the character described, comprising a backing, mold-sections removably supported by the backing, outwardly-extending projections carried by the outer faces, mold-sections adjacent their upper and lower edges, and having recesses in their sides adjacent the edge of the section, and stripe extending horizontally across the line of juncture of the sections and resting in the recesses in the lugs of the adjoining sections.

14. An apparatus of the character described, comprising a backing, mold-sections removably supported thereby, and locking-plates having longitudinal recesses in their upper and lower edges to receive the adjoining edges of the mold-sections, and locking the same together.

15. An apparatus of the character described, comprising a backing, mold-sections removably supported by the backing, outwardly-extending projections carried by the outer faces of the mold-sections adjacent their upper and lower edges and alternately carried by the upper and lowar sections, and having recesses in their faces adjacent the edge of the section, and elongated thin flat strips resting in the recess in the lugs of the adjoining sections and bearing against the outer faces of the sections.

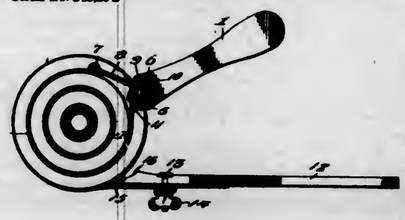
16. An apparatus of the character described, comprising a backing, mold-sections removably supported thereby, and locking-plates having longitudinally-extending recesses in their upper and lower edges of a size to snugly receive the straight smooth adjoining edges of the mold-sections and locking the same together.

812,007. **POTATO-DIGGER.** D O BOWMAN, Rockford, Mich. Filed Jan. 15, 1904. Serial No. 189,176.



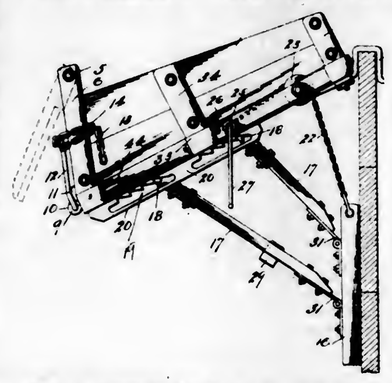
Claim.—A frame comprising pivotal front and rear sections, wheels mounted on the latter, a U-shaped axle mounted on the front section in close proximity to the pivotal connection of the frame, and wheels supported thereby, a segment carried by the front section and forming a bearing for the U-shaped axle, and a lever having means for engaging the segment to lock the axle in a raised or lowered position.

812,008. **WRENCH.** DANIEL BRAXTON, Baltimore, Md., assignor of one-third to Charles J. Dobler, Baltimore, Md. Filed Mar. 3, 1905. Serial No. 248,294.



Claim.—A jar-wrench comprising a handle formed at one end with a point, and with a curved surface projecting from said point, of a band bent laterally at said point, the free end of the band being bifurcated, and a set-screw carried by the handle to engage the walls of said bifurcation, said set-screw fixedly securing the opposite end of the band to the handle whereby to secure the band in adjusted position on the handle.

812,009. **CHUTE FOR UNLOADING RAILWAY-CARS.** JOSEPH H. BRASEAL, Birmingham, Ala. Filed Sept. 2, 1905. Serial No. 276,851.



Claim.—1. A portable chute for the purpose described, having means for attachment to a car, and having brace-stays adjustably connected to the chute, and adjustable braces extending from the stays to the chute, all combined.

2. A portable chute provided with hooks for attachment to a car, brace-stays flexibly connected to the chute and in position to rest against the car, and adjustable braces extending from said stays to the chute, all combined.

3. The combination with a portable chute, of brace-stays connected by flexible means to said chute, and braces hinged to the stays and engaging racks at the lower side of the chute.

4. The combination with a portable chute, of a pair of brace-stays connected thereto by the chains, a windlass on the chute by which said chains may be wound, and adjustable braces extending from the stays to the lower part of the chute.

5. The combination with a chute, of brace-stays connected thereto by chains, a windlass by which said chains may be wound, and adjustable braces interposed between said stays and the chute, substantially as described.

6. The combination with a chute, of brace-stays connected by chains to the lower part thereof, means for adjusting the effective length of said chains, braces hinged to said stays, and means for securing the ends of said braces remote from the stays to the chute in adjusted position.

7. The combination with a chute and means for suspending the same at the side of a car, of a gate hinged above the mouth of the chute, a rock-shaft having cranks which turn to position to hold the gate closed, and means for holding said rock-shaft.

8. The combination with a chute-body having a hinged gate at one side and suspending means at the other side, of brace-stays and braces attached to the said body to fold against the same for storage or transportation.

9. The combination with a chute and braces for supporting the same from the side of a car, of suspending-hooks adjustable longitudinally of said chute.

812,010. **JOINTED RULE.** DENNIS J. BRENNAN, Shenandoah, Pa. Filed Sept. 20, 1905. Serial No. 279,612.

Claim.—1. A jointed rule having a spring interposed between two of its jointed sections tending normally when the rule is closed to press said sections apart.

2. A jointed rule having a spring carried by one of two jointed sections and tending normally when the rule is closed to press said sections apart.

3. A jointed rule having one of two jointed sections provided with a recess, a spring secured on the inner edge of said section and having a free end portion working in said recess, and a projection

having its outer edge lying between said spring and the inner edge of the other section when the rule is closed and being carried by the other of said sections, whereby when said sections are closed the

812,012.

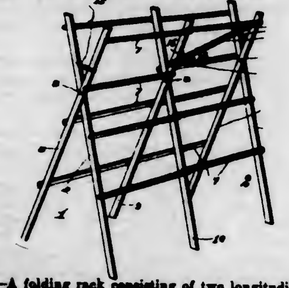
to the lower face of said seat approximately centrally at the front thereof and of greater length than the rear legs and adapted to rest

or locking-surfaces thereon, and supported on the upper part of the frame portion, and engaging the barrel extension at two places, and

having its outer edge lying between said spring and the inner edge of the other section when the rule is closed and being carried by the other of said sections, whereby when said sections are closed the spring will be depressed.

4. A jointed rule having one of two jointed sections provided with a recess, a spring secured to the inner edge of said section and having a free end portion working in said recess and provided with a projection extending beyond the inner edge of said section whereby when said sections are folded together the spring will be depressed by contact of the second section with said projection.

812,011. CLOTHES-FRAME. CHARLES W. BROSE, New Comerstown, Ohio. Filed Aug. 21, 1902. Serial No. 120,543.

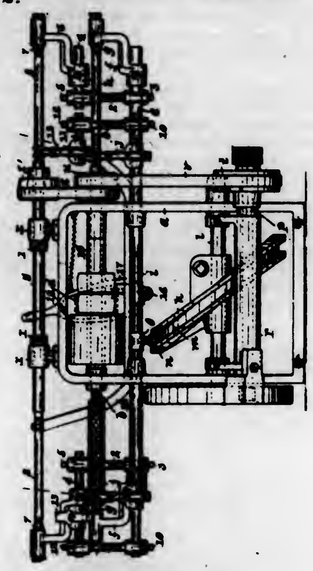


Claim.—A folding rack consisting of two longitudinally-foldable and laterally-spreadable sections, each section comprising a pair of uprights arranged side by side and pivotally joined together at points between their ends and a series of longitudinal members arranged on the outside edges of the said upright members on opposite sides of said pivotal connections and having their outer ends pivoted to said uprights, the inner ends of said longitudinal members which lie in approximately the same planes, being overlapped and pivoted to one of a pair of transversely-pivoted uprights which serve as a joining means for the two sections, each section having a single longitudinal member arranged in proximity to the transverse pivotal connections of the uprights, and on opposite sides of the frame from each other, and having their inner ends pivotally connected each to one of the aforesaid uprights joining the said sections together, respectively, substantially as set forth.

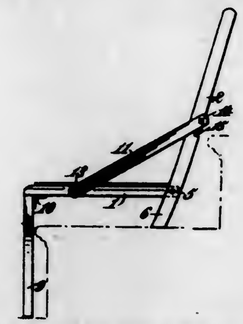
812,012. WINDING-MACHINE. GEORGE W. BROMLEY, Lake View, N. J. Filed Apr. 11, 1905. Serial No. 254,957.

Claim.—The combination of the frame, two rotary bobbin-driving shafts arranged parallel with each other, a traverse-rail, thread-guides, one for each shaft and one of them being carried by said traverse-rail, means for supporting the other thread-guide on said traverse-rail, a fixed shaft, a bracket carried by said fixed shaft, a stud arranged in said bracket and alined, and adapted to coact, with one of said rotary shafts to support a bobbin, an upright carried by said fixed shaft, a rod arranged in said upright, another bracket carried by said rod, another stud arranged in said last-named bracket and alined, and adapted to coact, with the other rotary shaft to support another bobbin, means for rotating said rotary shafts, and means for effecting the traverse of said traverse-rail, substantially as described.

812,012.



812,013. FOLDING STAIR-CHAIR. BERNET C. BROWER and JOHN D. H. SCHULS, Brooklyn, N. Y. Filed Aug. 26, 1905. Serial No. 275,262.



Claim.—1. A folding stair-chair comprising a seat, a pair of short rear supporting-legs pivoted to the sides of said seat, and a front supporting-leg hinged to the lower face of said seat approximately centrally at the front thereof and of greater length than the rear legs.

2. A folding stair-chair comprising a seat, a pair of short rear supporting-legs pivoted to the sides of said seat, a front supporting-leg hinged to the lower face of said seat approximately centrally at the front thereof and of greater length than the rear legs, and means to prevent the collapsing of the rear legs when the chair is extended.

3. A folding stair-chair comprising a seat, a pair of vertically-extending members pivoted at a point in proximity to the lower ends thereof to said seat and having that portion depending below said seat constituting a pair of short rear supporting-legs, a back-frame secured to said members, a front supporting-leg hinged to the lower face of said seat approximately centrally at the front thereof and of greater length than the rear legs, and means for retaining said members and back-frame in an upright position when the chair is extended.

4. A folding stair-chair comprising a seat adapted to be arranged over the top surface of a step, a pair of short rear supporting-legs pivoted to the said seat and adapted to rest upon the surface over which the chair-seat is arranged, and a front supporting-leg hinged to the lower face of said seat approximately centrally at the front thereof and of greater length than the rear legs and adapted to rest upon a surface below the plane of the surface over which the chair-seat is arranged.

5. A folding stair-chair comprising a seat adapted to be arranged over the top surface of a step, a pair of short rear supporting-legs pivoted to the said seat and adapted to rest upon the surface over which the chair-seat is arranged, and a front supporting-leg hinged to the lower face of said seat approximately centrally at the front thereof and of greater length than the rear legs and adapted to rest upon a surface below the plane of the surface over which the chair-seat is arranged, said front and rear legs of such length as to suspend the chair-seat at a point above the surface over which said seat is arranged.

6. A folding stair-chair comprising a seat adapted to be arranged over the top surface of a step, a pair of short rear supporting-legs pivoted to the said seat and adapted to rest upon the surface over which the chair-seat is arranged, a front supporting-leg hinged to the lower face of said seat approximately centrally at the front thereof and of greater length than the rear legs and adapted to rest upon the surface below the plane of the surface over which the chair-seat is arranged, and means to prevent the collapsing of said rear legs when the chair is extended.

7. A folding stair-chair comprising a seat, a pair of short rear supporting-legs pivoted thereto, a transversely-extending front supporting-leg arranged centrally of the said seat at the front thereof and having an enlarged top upon which said seat rests when the chair is extended, and a hinge for connecting the front leg to the seat, said hinge of a length equal to the length of the enlarged top of the leg.

812,014. STACKER FOR GRAIN OR THE LIKE. JOHN H. BULLOCK, Millerton, Kans. Filed June 24, 1905. Serial No. 266,770.

Claim.—1. A stacker for grain, comprising a substantially cylindrical base-section and a crown-section, the crown-section comprising a cylindrical portion for engaging into the base-section, and a conical portion having a base of greater diameter than the base-section and secured to the cylindrical portion, whereby to form an overhang at the edge of the crown of the stack.

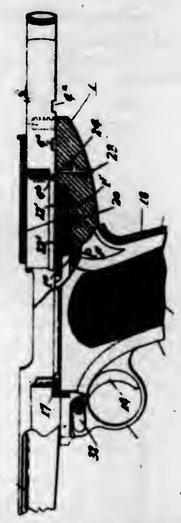
2. A stacker for grain, comprising a base-section and a crown-section, the grain-section comprising a cylindrical portion for engaging into the base-section, and a conical portion having a base of greater diameter than the base-section and secured to the cylindrical portion, whereby to form an overhang at the edge of the crown of the stack, the base-section being substantially cylindrical and of greater diameter at its top than at the bottom, whereby to form a tapering base for the stack.

812,015. RECOIL-OPERATED FIREARM. MARTIN BYE, Worcester, Mass., assignor to Harrington & Richardson Arms Company, a Corporation of Massachusetts. Filed July 23, 1904. Serial No. 217,241.

Claim.—1. In a firearm, the combination with the frame, the slidable barrel and barrel extension thereon, and the slidable breech-bolt within the barrel extension, of a positive locking-bolt for the breech-bolt, having two projections or locking-surfaces thereon, and supported on the frame, and engaging the barrel extension, and adapted to be moved into engagement with the breech-bolt to lock the same, and out of engagement therewith to release the same.

2. In a recoil-operated firearm, a positive sliding double locking-bolt for locking the breech-bolt in its forward position, said locking-bolt consisting of a plate having its central part open or perforated, and an extension at each end on one side forming the locking-surface, and each extension having one edge beveled, and said locking-bolt operated on the recoil of the barrel, to release the breech-bolt and allow its recoil.

3. In a recoil-operated firearm, the combination with a frame portion, a barrel, a barrel extension, and a breech-bolt slidable therein, of a positive slidable double locking-bolt, having two projections or locking-surfaces thereon, and supported on the upper part of the frame portion, and engaging the barrel extension at two places, and adapted to be moved by the movement of the barrel extension, into and out of engagement with the breech-bolt, at two places, to lock the same in its forward position, and to release the same, to be moved back to its rear position.



4. In a firearm, the combination with the barrel and barrel extension, the slidable breech-bolt, and the firing-pin therein, and actuating-springs for the breech-bolt and the firing-pin, within the breech-bolt, of a sear having a projection adapted to extend in the path of the firing-pin, a trigger, a trigger-pawl for engaging the sear to move it out of engagement with the firing-pin, and a slidable longitudinally-moving safety-bar adapted to engage the sear to prevent its movement, said safety-bar connected with and operated by a lever at the rear of the handle, and said lever.

5. In a firearm, the combination with the sear, and means to operate it to release the firing-pin to discharge the firearm, of a longitudinally-sliding safety-bar extending in a groove in the upper side of the frame, adapted to engage directly with the sear to prevent its operation, and a lever located at the rear of the handle and connected with said sliding safety-bar, to move the same and release the sear.

6. In a firearm, the combination with a sear, and means to operate it to release the firing-pin to discharge the firearm, of a longitudinally-sliding safety-bar moving in a groove in the upper side of the frame, and having a front hook end adapted to engage the sear to prevent its operation, and a lever located at the rear of the handle and connected with said sliding safety-bar, to move the same and release the sear.

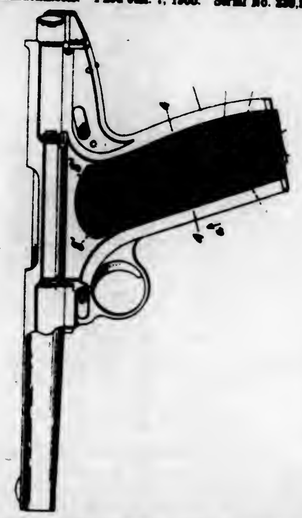
7. In a firearm, the combination with the sear, and means to operate it to release the firing-pin to discharge the firearm, of a longitudinally-sliding safety-bar, adapted to engage and lock the sear and prevent its operation, and a lever located at the rear of the handle and connected with said sliding safety-bar, to move the same and release the sear, and a rotary bolt having a projection thereon, and a thumb-lever attached to said bolt for operating the same, said projection adapted to be moved into engagement with the sliding safety-bar to lock the same, and prevent accidental discharge of the firearm, and to be moved out of engagement with the same to release the sliding bar.

8. In a firearm, the combination with the frame, and the slidable breech-bolt, of a slide at the rear of the handle, and away from and disconnected with the magazine, said slide having a reciprocating movement within the frame, with its outer engaging end extending through the lower side of the frame, at the rear of the handle, and held in its normal position by a spring, and adapted to be moved by the hand of the operator into engagement with the breech-bolt, when it is moved into its rearmost position, and held in engagement therewith, to lock the same.

9. In a firearm having a handle, the combination with the sear, and means to operate it to release the firing-pin to discharge the fire

arm, of a longitudinal sliding safety-bar, adapted to engage and lock the sear to prevent its operation, and a lever located in an opening at the rear of the handle and connected directly with said sliding safety-bar to move the same and release the sear, and said lever having projections thereon to engage recesses in the end of the handle, to detachably secure said lever to the handle.

812,016. **HANDLE FOR FIREARMS.** MARTIN BYE, Worcester, Mass., assignor to Harrington & Richardson Arms Company, a Corporation of Massachusetts. Filed Jan. 7, 1905. Serial No. 239,986.



Claim.—1. In a firearm, the combination with the handle portion, of detachable cheek-pieces having stationary headed screws or attaching devices upon their inner surface, adapted to engage recesses in the handle portion, to secure the cheek-pieces thereto, and means for holding said attaching devices in engagement with said recesses, said means comprising a plate on the outer or lower end of the handle portion, substantially as shown and described.

2. In a firearm, the combination with the handle portion, of detachable cheek-pieces having stationary headed screws or attaching devices upon their inner surface, adapted to engage recesses in the handle portion to secure the cheek-pieces thereto, and means for holding said attaching devices in engagement with said recesses, said means comprising a detachable plate on the outer or lower end of the handle portion, and means for attaching and detaching said plate, substantially as shown and described.

3. In a firearm, the combination with the handle portion, of a plate having a projection thereon to extend into a recess in the end of the handle, and a rotatable stud thereon, and a projection on said stud, and an external handle to rotate said stud and move said projection into and out of engagement with a recess in the end of the handle, to attach said plate thereto, and detach it therefrom, substantially as shown and described.

812,017. **PRESSURE-REGULATOR.** ALBERT B. CARMICHAEL, Westerly, R. I., administrator of Alexander Carmichael, deceased. Filed Jan. 16, 1905. Serial No. 241,469.

Claim.—1. In a piston having a passage, a soft disk having a corresponding passage and a follower counterbored as described, and a tube having a web near its mid-length combined and arranged to serve substantially as herein specified.

2. The tube M in separable parts of different diameter and one having a web M' in combination with a soft disk, having an aperture adapted to receive it, and with a piston and a follower having each a passage and one counterbored, all substantially as herein specified.

3. A soft disk having a thick segment and an aperture in combination with a short tube having a web near its mid-length and with a correspondingly-apertured piston and follower, one of which is recessed to match, all substantially as herein specified.

812,018. **METHOD OF AND MEANS FOR RAILWAY-TRACK CONSTRUCTION.** EDWARD R. CLEMENT, Washington, D. C. Filed Dec. 18, 1905. Serial No. 292,220.

Claim.—1. The method of laying surface-contact railway-track, comprising the following steps: first arranging supporting means to carry rails during construction approximately at their final level, second supporting the rails and contacts with the latter and the securing devices supported upon the rails, and third, building final supporting means under and about the rails and contacts, substantially as described.

2. The method of laying surface-contact railway-track which comprises the following steps: first excavating and laying feeder-conduit; second, laying temporary supports; third, laying rails on the temporary supports with permanent securing devices such as yokes carried upon them; fourth centering and supporting at level upon the rails, contact devices and their appurtenances; and fifth filling or building up about both rail-supports and contacts or their supports to produce an integral monolithic composition-body, substantially as described.

3. The method of laying electric-railway track which consists in suitably excavating, supporting the rails temporarily and the contact apparatus upon the rails or rail-supports and building up around the whole a permanent supporting-body, substantially as described.

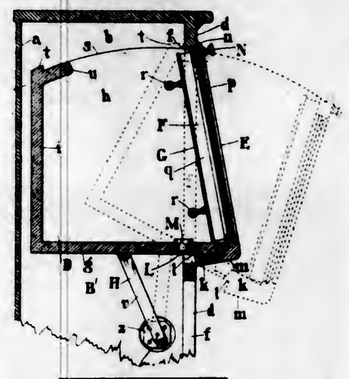
4. Apparatus for laying electric-railway track, comprising temporary rail-supports, and contact-supports, each with adjustable securing means, substantially as described.

5. Apparatus for railway construction comprising the channel-beam, with central holding means and adjustable securing means for attachment to the rails, substantially as described.

6. The apparatus described for constructing electric-railway track comprising the temporary rail-supports, and the channel beams or gages having approximately central securing means for the contacts or their supports, and terminal means for attachment to the rails or the supports thereof, substantially as described.

812,019. **BIN.** CHARLES COBBS, New York, N. Y. Filed Sept. 12, 1903. Serial No. 172,803.

Claim.—In bins the combination with a case having an opening in the front and a compartment in the rear of the opening, and a bin housed in the compartment and adapted to be swung in and out of the same, pivoted supports for the bin consisting of arms each of which has a part parallel to and rigidly fastened to the bottom of the bin and a downwardly-inclined part the lower end of which is extended downward below the bottom of the bin and pivotally connected to a plate let into the side of the case below the compartment to facilitate the detachment of the bin from the case and its removal therefrom, substantially as specified.



812,020. **EMBALMING-CATHETER.** HENRY M. CRIPPEN, Ballston Spa, N. Y., assignor to The Max Huncke Chemical Co., Brooklyn, N. Y. Filed Nov. 4, 1905. Serial No. 285,859.

Claim.—1. A catheter of the character specified, comprising a tube and a flexible member, and an outer slidable shield thereon.

2. A catheter of the character specified, comprising a tube and a coil-spring member, and an outer slidable shield thereon.

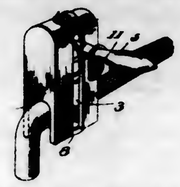
3. A catheter of the character specified, comprising a tube and a flexible member, an outer slidable shield thereon, and an elastic sleeve engaging the inner end of the shield and the tube, whereby to prevent leakage therebetween.

4. A catheter of the character specified, comprising a tube and a coil-spring member, an outer shield slidable thereon, and a sleeve engaging the end of the shield and the tube for preventing leakage of matter from between the inner end of the shield and the tube.

5. A catheter of the character specified, comprising a tube and a flexible member, and an outer slidable shield provided with a sleeve at the inner end thereof for engaging the tube.

6. A catheter of the character specified, comprising a tube and a flexible member, an outer sheild slidable thereon, and a sleeve of an elastic member surrounding the joint between the tube and the inner end of the shield, a portion of which fits upon the tube and the remaining portion of which fits upon the inner end portion of the shield.

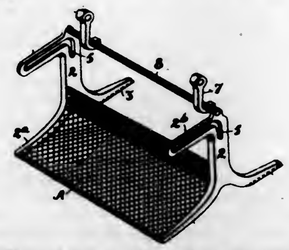
812,021. **FAUCET-LOCK.** WILLIAM T. DAHL, Bottineau, N. D. Filed Sept. 15, 1904. Renewed Nov. 4, 1905. Serial No. 285,988.



Claim.—1. A faucet-lock comprising a block open at bottom, the front and rear walls being recessed to straddle and rest upon the body of the faucet and support the lock, the side wall of the block being bifurcated to receive the key of the faucet, the walls of said bifurcation engaging the wing of the faucet-key and preventing movement thereof.

2. As an article of manufacture, a faucet-lock consisting of a hollow block open at the lower end and having a side wall slotted longitudinally from the lower end upwardly to snugly receive the faucet-key to hold the same against movement, said faucet-key adapted to project outwardly between the walls of the slot and below the upper end thereof, the front and rear walls of said block being longitudinally slotted for a comparatively short distance upwardly to snugly straddle the faucet-body and thereby center the block thereon and hold the same against horizontal oscillation, substantially as described.

812,022. **CAR FENDER AND BRAKE.** LEE A. DEVIN, San Francisco, and FRANK S. ATKINS, Oakland, Cal. Filed Nov. 6, 1905. Serial No. 285,969.



Claim.—1. The combination with a car having projections on its sides, of an emergency-brake comprising a frame having rearwardly-extending shoes adapted to contact with the track-rails said frame slidably guided by said projections, and mechanism by which said frame may be moved to project the shoes beneath the wheels of the car.

2. The combination with a car having projections on its sides, of a protective device comprising a fender and emergency-brake said brake including side frames and means for suspending them from the car, said frames having substantially horizontal channels receiving said car projections, and having, also, rearwardly-extending track-shoes, and a lever and connections by which the fender and brake may be moved substantially horizontally, and the track-shoes projected beneath the wheels of the car.

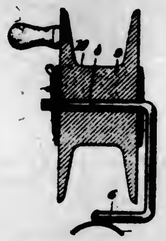
3. In a car fender and brake, side frames having front fender-supporting extensions and rearwardly-extending track-shoes, and slotted suspending-arms at the top, fixed pins extending into the slots, hangers and a lever connected therewith by which to raise and lower and move the fender horizontally.

812,028. **FISHING-REEL.** FREDERICK L. DICKSON, El Paso, Tex. Filed Feb. 21, 1905. Serial No. 246,696.

Claim.—1. In a device of the class described, in combination, a bracket having a body adapted to be attached to a rod, said body having a laterally-disposed arm integral therewith, a disk collar of enlarged diameter rigidly attached to said arm adjacent to said body, and a reel rotatably mounted on said arm and abutting against said collar.

bearing and to counteract its tendency to rotate with the spindle, | spect to the perforations and jam-nuts for locking the said members

2. In a device of the class described, in combination, a bracket adapted to be attached to a rod and presenting a laterally-disposed arm, a reel rotatably mounted upon said arm, said arm having an extension beyond said reel with an opening therethrough, a collar mounted upon said arm adjacent to the face of said reel, and a tapered pin engaging said collar and preventing rotation thereof, said tapered pin passing movably through said opening and retaining said reel.



3. In a device of the class described, in combination, a bracket adapted to be attached to a rod and presenting a laterally-disposed arm with an opening near the extremity thereof, a reel rotatably mounted upon said arm, a collar mounted upon said arm adjacent to said opening, said collar having an eye on the outer face thereof, and a tapered pin passing through said eye and through said opening.

4. In a device of the class described, in combination, a bracket adapted to be attached to a rod and presenting a laterally-disposed arm with an opening at the extremity thereof, a reel rotatably mounted upon said arm, a collar mounted upon said arm adjacent to the outer face of said reel, said collar presenting an eye on the outer face thereof, and a tapered pin having a hooked extremity passing through said eye and said opening, said pin affording means for retaining said reel and locking said collar against rotation.

5. In a device of the class described, in combination, a bracket adapted to be attached to a rod and presenting a laterally-disposed arm, a collar fixed near the inner extremity of said arm, a reel mounted rotatably upon said arm and abutting on said collar, said arm projecting beyond said reel and having an opening therethrough, a second collar mounted upon said arm and abutting on the outer face of said reel, said second collar having an eye on the outer face thereof, and a pin passing through said eye and said opening, said pin affording means for locking said reel.

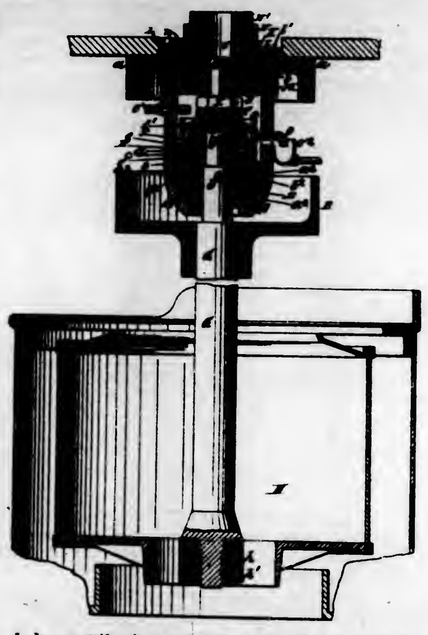
812,024. **MEANS FOR HANGING OVERDRIVEN CENTRIFUGAL MACHINES.** GEORGE DUNKEL, Jersey City, N. J. Filed Jan. 27, 1904. Serial No. 190,893.

Claim.—1. In a centrifugal apparatus, the combination of a universal joint, a bearing supported upon and supplemental to said universal joint above the hemispherical center thereof, a spindle suspended upon said universal joint and rotatable upon said bearing, the suspension of said spindle being directly on said bearing, and means receiving the upper end of the spindle and forming a support for a buffer.

2. In a centrifugal apparatus, the combination of a universal joint, a bearing supported upon and supplemental to said universal joint above the hemispherical center thereof, a spindle suspended upon said universal joint and rotatable upon said bearing, the suspension of said spindle being directly on said bearing, and means receiving the upper end of the spindle and forming a support for a buffer, and a resilient buffer through which said means passes, said buffer constructed to centralize the shaft without interfering with its rotation.

3. In a centrifugal apparatus, the combination of a universal joint and a roller-bearing above the same, a spindle suspended upon said universal joint and rotatable upon said bearing, said bearing being supplemental to and disposed above the hemispheric center of said universal joint, means receiving freely the upper end of said spindle, means engaging said spindle between said bearing and said first-mentioned means, and a buffer surrounding and supported by said first-mentioned means.

4. In a centrifugal apparatus, the combination of an antifriction-bearing and a universal joint, a spindle suspended upon said universal joint and directly rotatable upon said bearing, said bearing being supplemental to and supported on said universal joint above the hemispheric center thereof, a resilient buffer around the upper end of the said spindle for centralizing the same, means surrounding the upper end of said spindle and extended through said buffer, and means cooperating with the hemispherical bearing and disposed at right angles to the length of the spindle to restrict the oscillation of said bearing and to counteract its tendency to rotate with the spindle.



5. In a centrifugal apparatus, the combination of an antifriction-bearing and a universal joint, a spindle suspended upon said joint and directly rotatable upon said bearing, said bearing being supplemental to and supported on said universal joint above the hemispheric center thereof, a resilient buffer around the upper end of said spindle for centralizing the same, means surrounding the upper end of said spindle and extended through said buffer, and means cooperating with the hemispherical bearing and disposed at right angles to the length of the spindle to restrict the oscillation of said bearing and to counteract its tendency to rotate with the spindle.

6. In a centrifugal apparatus the combination of a spindle suspended upon a universal joint and rotatable upon a bearing supported upon said universal joint above the hemispheric center thereof, said bearing of rotation and said universal joint, a resilient buffer surrounding the end of said rotatable spindle above its center of suspension, a bushing interposed between said upper end of the spindle and the resilient medium, said bushing being formed at its lower extremity with a flange having a convex surface concentric with the said center of suspension, and a bearing-plate interposed between said convex surface of the flange and the resilient medium, said bearing-plate being formed with a concave surface concentric to said center of suspension.

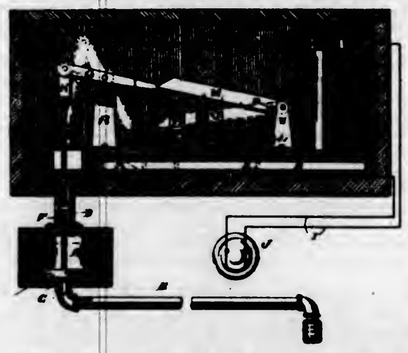
7. In a centrifugal apparatus, the combination of an antifriction-bearing and a universal joint, a spindle suspended upon said universal joint and directly rotatable upon said bearing, said bearing being supplemental to and supported on said universal joint above the hemispheric center thereof, a resilient buffer around the upper end of said spindle for centralizing the same, means surrounding the upper end of said spindle and extended through said buffer, and means cooperating with the hemispherical bearing and disposed at right angles to the length of the spindle to restrict the oscillation of said bearing and to counteract its tendency to rotate with the spindle.

8. In a centrifugal apparatus, the combination of an antifriction-bearing and a universal joint, a spindle suspended upon said universal joint and directly rotatable upon said bearing, said bearing being supplemental to and supported on said universal joint above the hemispheric center thereof, a resilient buffer around the upper end of said spindle for centralizing the same, means surrounding the upper end of said spindle and extended through said buffer, means cooperating with the hemispherical bearing and disposed at right angles to the length of the spindle to restrict the oscillation of said bearing and to counteract its tendency to rotate with the spindle, said spindle being hung from a central point with which all bearing-surfaces are concentric, and a bearing-plate for said buffer, having a curved bearing on the means which passes through said buffer.

9. In a centrifugal apparatus, the combination of a universal joint, a roller-bearing supported upon and supplemental to said universal joint, a spindle suspended upon said universal joint, and rotatable on said bearing, and a resilient buffer surrounding the upper end of said spindle, and extended above the same.

10. In a centrifugal apparatus, the combination of a universal joint, and a roller-bearing supported upon and supplemental to said universal joint, a spindle supported upon and suspended from said universal joint and rotatable on said bearing, a resilient buffer surrounding the upper end of the spindle and extended above the same, and means beneath said bearing and cooperating with said joint to counteract the tendency of said spindle to oscillate laterally.

812,025. **SIGNAL.** CHARLES R. DOWLER, Lamar, Colo., assignor to The Colorado Railway Signal Company, a Corporation of Colorado. Filed Jan. 14, 1905. Renewed Dec. 18, 1905. Serial No. 292,272.



Claim.—1. The combination in a signal, of a box having an opening wherethrough fluid may enter into the box, a float in the box, a circuit-closer adapted for operation through rising action of the float, an electrical circuit having a battery and signal device therein, and means whereby the circuit-closer may be held set ready for operation through suitable connection, upon the next rising action of the float.

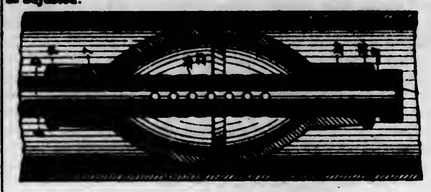
2. The combination in a signal, of a box suitably located at high-water level, a pipe extending from the box to position adapted to lead the high water into the box, a float in the box, a rod extending from the float, circuit-closing means wherewith the far end of said rod is connected, circuit-wires, a battery and a signal device, and means whereby the circuit-closer may be held set adapted to be operated by rising action of the float substantially as described.

3. The combination in a circuit-closer, of circuit-terminals, an arm yieldingly held at circuit-closing position, a free acting dog whereby said arm may be held out of circuit-closing position, means adapted to lift the circuit-closing arm to normal open-circuit position, and means operating the lifting-arm, substantially as described.

4. The combination in a signal employing a float and suitable connecting means, of a circuit-closer adapted for operation by a float and its connections, the circuit-closer consisting of an oscillating arm adapted for operation through the float connections, circuit-terminals, an arm yieldingly held completing circuit through the terminals, a dog whereby the circuit-closing arm may be held at open-circuit location and in position for engagement thereof by the free end of the oscillating arm, substantially as described.

812,026. **EJECTOR.** CHARLES A. DEVER, Champaign, Ill. Filed May 23, 1905. Serial No. 261,734.

Claim.—The combination with a well-tube of a fluid-pressure tube extending into the well-tube and having a plurality of perforations near the lower end, a cap having screw-threaded engagement with the lower end of the pressure-tube for closing the same, a head comprising cup-shaped members having screw-threaded engagement with said pressure-tube, the adjacent open ends of said members being spaced apart to form an annular port, the walls thereof being inclined upward and outward, the said port being centrally arranged with respect to the perforation and jam-nuts for locking the said members as adjusted.



812,027. **FIBROUS PLASTIC RAILWAY-TORPEDO.** FRANK DUTCHER, Versailles, Pa. Filed Aug. 31, 1905. Serial No. 276,389.

Claim.—1. An improved railway-torpedo made of a denotating compound when in a plastic state, and a separate inclosing case therefor.

2. An improved railway-torpedo made of a detonating compound when in a plastic state, and a waterproof inclosing fibrous case therefor.

3. An improved railway-torpedo, comprising a fibrous containing-case, a detonating compound placed within the case when in a plastic condition, and an inclosing fibrous case for said containing-case.

4. An improved railway-torpedo, comprising a fibrous containing-case, a detonating compound placed within the said case when in a plastic condition, a fibrous inclosing case, and means for connecting the inclosing case with the containing-case.

5. An improved railway-torpedo, comprising a fibrous containing-case, a detonating compound placed within the case when in a plastic condition, and a fibrous inclosing case connected with the containing-case.

6. An improved railway-torpedo, comprising a flanged fibrous containing-case, a detonating compound placed within the case when in a plastic condition, a flanged inclosing case, the flanges of the two cases being connected together.

7. An improved railway-torpedo, comprising a fibrous flanged containing-case, a detonating compound placed within the containing-case when in a plastic condition, a flanged inclosing case, and a holding means surrounding the flange of the inclosing case.

8. An improved railway-torpedo, comprising a fibrous case, a detonating compound therein, and a strap-attaching member consisting of an elongated plate having ends passing through the case and bent downward upon the inner side thereof, and clamping the strap between it and the outer side of the case.

9. An improved railway-torpedo, comprising a fibrous case, a strap-attaching member extending to the inside of the case, a detonating compound within the case, and a fibrous disk between the detonating compound and the said strap-attaching member.

812,028. **FLASH-LIGHT COMPOSITION.** ARTHUR HOMBERGER, Elberfeld, Germany, assignor to Farbenfabriken of Elberfeld Co., New York, N. Y., a Corporation of New York. Filed June 17, 1905. Serial No. 265,306.

Claim.—1. The herein-described new flash-light powders being prepared from metallic powders, which have a strong affinity for oxygen and are therefor easily combustible and the combustion of which produces a light of great intensity, with tungstic acid and derivatives, which flash-light powders burn slowly in comparison to the ordinary flash-lights for instantaneous exposure and produce great luminosity, substantially as described.

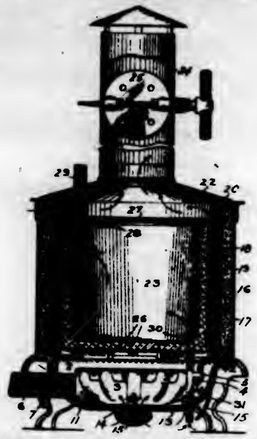
2. The herein-described new flash-light powder being a mixture of magnesium with tungstates, substantially as described.

812,029. **KILN.** HENRY T. HYMANSON, San Francisco, Cal., assignor of one-half to George W. Clarke, East Liverpool, Ohio. Filed June 10, 1905. Serial No. 264,963.

Claim.—1. In a kiln, the combination with a suitable base, of a

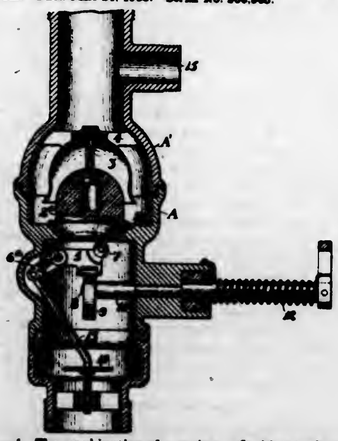
3. In a device for controlling the flow of water, a pipe and casing

Claim.—1. In a kiln, the combination with a suitable base, of a gas-burner, a jacket, and a fire-pot within said jacket, said fire-pot having a thick bottom and walls tapering in thickness toward the top.



2. In a kiln, combination with suitable base, of a gas-burner, an inclosed heating-chamber having a flue leading therefrom, a damper controlling said flue, a fire-pot within said chamber, means for admitting air to said fire-pot from below, a cover for said fire-pot, and a pipe leading from said fire-pot and passing out through the walls of said fire-chamber to the atmosphere.

812,080. FLUSHING-TANK VALVE. JOB E. ERICSON, San Francisco, Cal. Filed June 26, 1905. Serial No. 266,963.



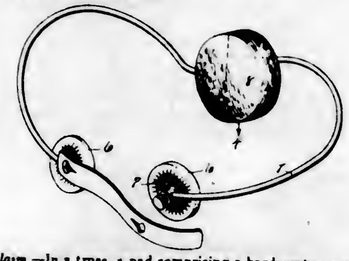
Claim.—1. The combination of a casing, a flushing-tank valve, a seat upon which the valve is closable, a hood located above the valve and within which the valve lies when opened, said casing having a passage which surrounds the hood and through which the flushing-water passes without pressure upon the valve, and means for opening the valve said means including a pivoted lever below the valve and having one portion to contact therewith to lift the valve, and a member suspended from the opposite portion of the lever in the path of the rush of water whereby said member is actuated by the water-flow to hold the valve open until the water is discharged.

2. In a flushing apparatus, a pipe and casing through which the water is discharged, a hood located in the upper part of the casing and having an annular passage for the water around it, a valve-seat located below the hood, a valve reciprocable between the seat and the hood, a lever-arm below the valve having one end to engage said valve whereby the valve is raised from its seat into the hood, and means carried by the other end of the lever-arm and actuated by the water-flow by which the valve is held until the water is discharged.

3. In a device for controlling the flow of water, a pipe and casing through which the water flows, a valve-seat located within the casing, a vertically-movable valve closable upon the seat, a hood fixed above the valve when opened, said hood having an annular water-passage around it, a fulcrumed lever, one end of which contacts with the valve to open it, means carried by the other end of the lever and within the path of the flowing water whereby the valve is retained in an open position during said flow.

4. In a flushing and like device, a passage and casing through which the water is delivered, a valve-seat located within the casing, a rising and falling valve closable upon the sea, means for opening said valve, said means comprising a fulcrumed lever, one end of which contacts with the bottom of the valve, a shaft having a cam or eccentric contacting with said lever, said shaft being rotatable so that the cam will act through the lever to open the valve, a rod suspended from the opposite end of the lever carrying a disk in the path of the flowing water so that the pressure upon the disk will hold the valve open, and a hood located above the valve, within which the valve is protected during the flowing of the water.

812,081. TRUSS. GEORGE M. FARLINGER, Rossland, Canada, assignor to C. B. Heard, Victoria, British Columbia, Canada. Filed Apr. 27, 1905. Serial No. 257,791.



Claim.—In a truss, a pad comprising a hard center, a yielding ring surrounding the same, a covering for said center and ring passed around the center and ring and interposed between the two and doubled upon itself at the acting face of the pad, and a soft covering over said ring and covering, all substantially as shown and described.

812,082. LUBRICATOR. JOHN C. FICKES, Steubenville, Ohio, assignor to Buckeye Lubricating Company, Steubenville, Ohio, a Corporation of Ohio. Filed Aug. 4, 1905. Serial No. 272,709.

Claim.—1. In a lubricator, the combination with a suitable reservoir having a drain-opening and sight-openings, of a detachable head carried by said reservoir, said head having a condensing-chamber formed therein with a suitable opening, said head having an opening formed therein in substantially horizontal alinement with said opening, a steam-pipe extending through said head into said reservoir, an oil-receptacle carried by said head and communicating with said reservoir, said head having vertically-disposed ports formed therein, and communicating with said chamber, a pipe carried by said head and communicating with one of said ports and extending downwardly into said reservoir, said head having a cleansing-port formed therein, needle-valves controlling the first-named ports, sight-glasses carried by said head, substantially as described.

2. In a lubricator, the combination with a suitable reservoir adapted to contain a premelted lubricant, of a head having a lubricant-receptacle formed therein, said head having a chamber formed therein, said head having a plurality of ports formed therein, establishing communication between said reservoir and said chamber, said head having an outlet-opening and said chamber having an opening at its top in substantially horizontal alinement with the outlet-opening of the head, means to separately control the communication between the chamber and the reservoir through said ports, and a steam-pipe extending through said lubricant-receptacle and through a port establishing communication between said receptacle and said reservoir to heat the lubricant in said receptacle.

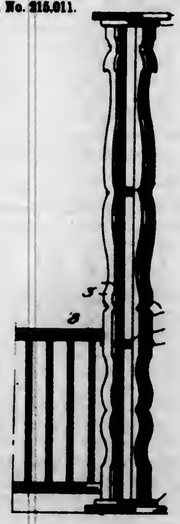
3. In a lubricating device, the combination with a reservoir having a detachable head, of a chamber formed in said head, and having an opening in its top, said head being provided with an opening disposed in substantially horizontal alinement with the opening in the top of said chamber, and said head being formed with a port extending from the chamber to the reservoir, a pipe extending into said reservoir and adapted to convey steam thereto, and means for controlling the passage of condensed steam from the reservoir into the chamber, through the said ports.

4. In a lubricating device, the combination with a reservoir and a detachable head mounted on said reservoir, said head being formed with a central chamber having an opening at its top, said head being also formed with a lateral opening in substantial alinement with the opening at the top of said chamber and said head being formed with an oil-receptacle disposed at one side of said chamber and with ports leading from said chamber to said reservoir and from said receptacle to said reservoir, of a steam-pipe passing through said receptacle and through the port leading from said receptacle to the reservoir, said head being formed with a by-pass port leading from said reservoir to the space between the lateral opening in the head and the opening at the top of said chamber.

5. In a lubricator, the combination with a suitable reservoir of a detachable head carried by said reservoir, said head having a condensing-chamber formed therein and with an opening in its top, said head having an outlet-opening disposed in substantially horizontal alinement with the opening in the top of said chamber, an oil-receptacle formed integral with said head, and communicating with said reservoir, said head being formed with a vertically-disposed port providing communication between the reservoir and chamber, and said head being provided with a port leading from the reservoir to a point between the opening in the top of the chamber and the outlet-opening of said head.

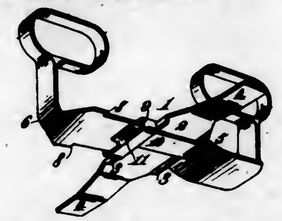
6. In a lubricator, the combination with a suitable reservoir of a detachable head carried by said reservoir, said head having a condensing-chamber formed therein and with an opening in its top, said head having an outlet-opening disposed in substantially horizontal alinement with the opening in the top of said chamber, an oil-receptacle formed integral with said head, and communicating with said reservoir, said head being formed with a vertically-disposed port providing communication between the reservoir and chamber, and said head being provided with a port leading from the reservoir to a point between the opening in the top of the chamber and the outlet-opening of said head, and a pipe carried by said head and extending from said port to a point adjacent the bottom of said reservoir.

812,083. COLUMN. ALONZO H. FLOWERS, Miami, Fla. Filed July 1, 1904. Serial No. 215,011.



Claim.—A column comprising a plurality of longitudinal bars having flat sides and continuous straight inner edges, the bars being also provided with edgewise openings extending transversely through the same, solid spacing-blocks having on their peripheries squared bearings arranged at suitable distances apart so as to contact with the straight inner edges of the bars, said blocks being provided with openings extending into their solid body portions, said openings coinciding with the openings of the bars, bolts secured in the openings of the bars and those of the blocks to permit of the flat sides of the bars being spaced at equal distances apart throughout their entire lengths, the bars being further provided on opposite ends with disks and supporting-blocks, and said bars when secured to the blocks having their surrounding front face edges extending outwardly, substantially as specified.

812,084. REIN-HOLDER. ISHAM G. FORSHEE, Versailles, Ky. Filed Aug. 29, 1905. Serial No. 276,304.



Claim.—1. A rein or line holder having a longitudinal base-support, a cross-support engaging the base-support and formed with reduced extremities continued into inwardly-projecting horizontally-disposed loops which are held at an elevation above the said cross-support, an under clasp secured at one extremity, and means for detachably securing the free extremity of said clasp.

2. A rein or line holder having oppositely-disposed rein-loops, and a clasp secured to the under portion thereof to removably engage a part of the harness.

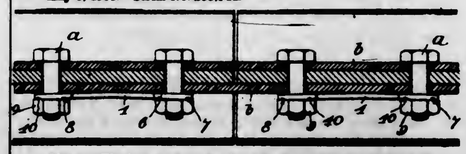
3. A rein-holder having rein-loops, a resilient clasp extending across the under portion of the same and secured at one end, and means for detachably securing the free end of said clasp.

4. A rein-holder having rein-loops and a lower longitudinally-extending seat, a clasp extending across the seat, and means for detachably securing one end of the clasp.

5. A rein-holder having a longitudinally-disposed base-rest formed with an under seat and tongues at its opposite extremities, a cross support intersecting the base-rest and provided with reduced extremities continued into inwardly-projecting horizontally-disposed rein-loops, a clasp extending across the under portion of the base-rest, and a loop slidable on part of the cross-support to detachably engage one end of the clasp.

6. A rein-holder having a longitudinally-extending base-support, a cross-support engaging the base-support and provided with reduced extremities bent upwardly and continued into inwardly-projecting rein-loops, a portion of the cross-supports having outer stop-shoulders, a box-loop slidable on the portion of the support having the stop-shoulders, and a resilient clasp extending across the under side of the base-support, the box-loop being movable over the free extremity of the clasp.

812,085. NUT-LOCK. JAMES W. FRANKLIN, Boston, Ga. Filed May 5, 1905. Serial No. 259,944.



Claim.—The herein-described nut-lock, consisting of the spring-washer made from a rod 1 of steel and having its intermediate portion bent reversely, as at 2, 3 and having its end portions oppositely curved to form the openings 5 for the bolts *a*, said oppositely-curved portions being provided with notches 6, said notches each having an abrupt shoulder 7 and an inclined portion 8, in combination with the bolts *a* and nuts 9, said nuts each having upon their inner face pro-

jections 10 which register with and engage the notches 6, said projections each having an inclined face and an abrupt shoulder to engage and fit the notches 6, essentially as described.

812,086. SHUTTER-BOWER. JOHN L. GUYOT, Mount, Pa. Filed Oct. 15, 1904. Serial No. 228,579.

Claim.—1. A shutter-bower comprising two pivoted bars adjustable on their pivots to different inclined positions vertically and laterally with relation to the shutters, one of said bars being provided with notches or seats and spaced retaining-hooks and the other with a hook to engage said notches or seats and adapted to be held in alinement with the first-named member by the retaining-hooks thereon.

2. A shutter-bower comprising two pivoted members adjustable on their pivots to different inclined positions with relation to the shutters, one of said members being provided in its upper edge with a series of keepers and the other with a latch-hook projecting rearwardly from its upper edge to engage said keepers to connect the two members together in a variety of positions, the said member having the keepers further being provided with forwardly-projecting upper and lower retaining-hooks disposed in close relation but at different distances from the free extremity of said member, said hooks being adapted to engage the latch-hook-carrying member when said latch-hook is engaged with one of the keepers to hold the members rigidly connected, said retaining-hooks having their adjacent edges beveled to form an interposed throat extending diagonally to the axis of the keeper member, substantially as and for the purpose described.

812,087. VEHICLE. JOHN H. HARRON and JOHN J. PETRABORG, Aitkin, Minn. Filed Feb. 23, 1905. Serial No. 246,371.

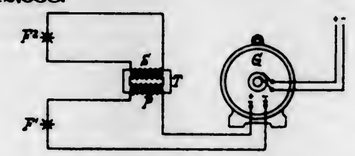
Claim.—1. The combination with a vehicle-body, of side bars and end bars pivotally connected at their ends to one another, and each pivotally connected intermediate its ends to the vehicle-body.

2. The combination with a vehicle-body, of side bars and end bars each pivoted centrally to the respective sides and ends of the vehicle-body, and being pivotally connected with one another, and supports for the vehicle carried by sundry of said bars.

812,088. REGULATION OF ELECTRIC CURRENTS WHICH FEED ELECTRIC ARCS. JOHANNES ERICHSEN, Ludwigshafen-on-the-Rhine, Germany, assignor to Badische Anilin & Soda Fabrik, Ludwigshafen-on-the-Rhine, Germany, a Corporation. Filed Nov. 23, 1904. Serial No. 234,503.

Claim.—The process of supplying currents to a plurality of circuits containing arcs suitable for the production of compounds of nitrogen and oxygen with the minimum displacement of phase, which consists in generating an alternating current, supplying therewith the primary of a transformer and an arc, and feeding a different arc with the secondary current from the transformer.

812,088.

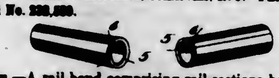


812,089. RAIL-JOINT. DAVID HEWITT, Homewood, Pa. Filed Oct. 26, 1905. Serial No. 284,462.

Claim.—1. In a rail-joint, the combination with rails having a single row of recesses formed centrally of in the bottom of the base-flanges, of a chair having openings formed therein, a single row of centrally-disposed pins carried by said chair and adapted to extend into the recesses of said rails, said chair having a flanged edge, an angularly-disposed flange carried by the opposite edge of said chair, fish-bars engaged by said chair and adapted to support rails mounted upon said chair, one of said fish-bars having its edge cut away to receive the flange on one side of the base-plate, the other of said fish-bars having notches in its edge registering with the openings in the chair and means to secure one of said bars in engagement with said chair, substantially as described.

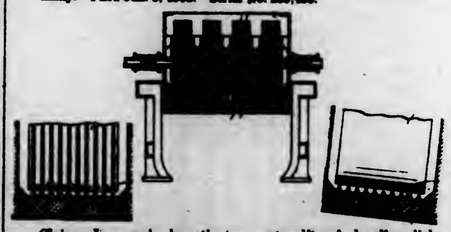
2. In a rail-joint, the combination with rails having recesses formed therein, of a chair, pins carried by said chair and adapted to engage in said recesses, flanges carried by the edges of said chair, fish-bars engaging said flanges and supporting the confronting ends of said sections of rails upon said chair, one of said fish-bars having its edge cut away to receive the flange at one edge of said chair, the other of said fish-bars having notches in its edge and means to lock said fish-bars in engagement with said chair, substantially as described.

812,040. RAIL-BOND FOR STREAM AND ELECTRIC RAILWAYS. FRANK C. HOFFMAN, Somerville, N. J. Filed Nov. 12, 1904. Serial No. 232,599.



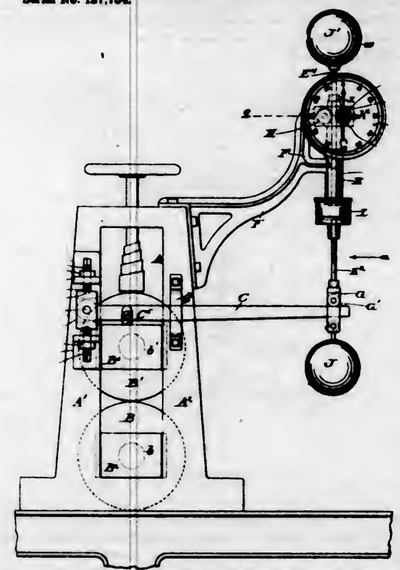
Claim.—A rail-bond comprising rail-sections having the webs of their meeting ends provided with tapered openings therein, split sleeves having cut-away overlapping edges mounted in said openings, a wire having angular bent ends, said ends passing through said sleeves, and said sleeves serving to be forced or driven into said openings to tightly embrace the inclosed ends of the wire which action also permits of said sleeves being capable of conforming to the configuration of said tapered openings in said webs, substantially as specified.

812,041. DECORTICATOR. FRANZ HOLTHAUSEN, Hessen, Germany. Filed Jan. 3, 1905. Serial No. 239,469.



Claim.—In a grain-decorticator, a plurality of abrading-disks mounted on a horizontal shaft, ribs on said disks in line with the direction of rotation of the disks, a set of stationary segments cooperatively arranged beneath the disks and being provided with parallel ribs on their surfaces adjacent the disks, said ribs of the segments extending slightly transversely to the direction of rotation of the disks, for the purpose specified.

812,042. DEVICE FOR MEASURING THE THICKNESS OF PAPER. BENJAMIN S. HUDSON, Castleton, N. Y. Filed Oct. 17, 1902. Serial No. 127,754.



Claim.—1. In a device for measuring the thickness of a running web of paper while moving between the finishing-cylinders of a calendering-machine, the combination with a movable part of a calendering-machine, a scale comprising marks of divisions and subdivisions, a pointer adapted to be brought to marks or points on said scale which arbitrarily indicate thickness, a pivoted lever connected to the movable part of the calendering-machine, a reservoir containing fluid, means intermediate the lever and the reservoir for forcing the fluid against a piston and a piston operatively connected with the pointer, the movement of the lever forcing the fluid against the piston to bring the pointer and a thickness-mark on the scale into correspondence when the lever is moved.

2. In combination, a calendering mechanism having actuating mechanism, an indicator, indicator-actuating mechanism, a fluid-reservoir of larger area than the end of the actuating mechanism and coöperating therewith, a piston in said reservoir which is disconnected from the end of the actuating mechanism, a rod connected therewith, and a pivoted lever connected with the rod and actuated by the actuating mechanism on the calendering mechanism, the indicator registering the thickness of the paper.

3. In combination, a calendering mechanism, an indicator, mechanism for operating the indicator, a fluid-reservoir of larger area than the end of the mechanism which operates the indicator and operatively connected therewith, a piston in said reservoir which is disconnected from the end of the latter actuating mechanism, a rod connected with the piston, and a pivoted lever connected with the rod and actuated by the calendering mechanism, the indicator registering the thickness of the paper.

4. In combination, a calendering mechanism having a movable part, an indicator, a roller connected to the pointer of the indicator, a rod contacting with said roller, a piston at the end of the rod, a fluid-reservoir of larger area than the piston and coöperating therewith, a piston in the reservoir, a piston-rod connected therewith, and a pivoted lever actuated by the movable part of the calender mechanism as the paper passes through the same, the movement of the lever indicating at the indicator the thickness of the paper.

5. In combination, a calender mechanism, an indicator, a roller connected to the pointer of the indicator, a rod contacting with said roller, a weight on the upper end of the rod, a piston at the opposite end of the rod, a cylinder in which the piston operates, a fluid-reservoir of larger area than the piston, a piston in the reservoir, a rod connected to said latter piston, a weight at the end of the rod, a pivoted lever actuated by the calendering mechanism, the movement of the lever indicating at the indicator the thickness of the paper.

6. A device for measuring the thickness of paper comprising a frame, an indicator bearing scale-marks, a pointer coöperating with the scale-marks, a roller secured to the pointer, a rod engaging the periphery of the roller, a cylinder in which the end of the rod operates, a reservoir containing fluid and communicating with the cylinder, a piston in the reservoir and means for connecting the piston with a paper-treating machine, whereby the thickness of the paper being treated will cause the piston to force the fluid against the rod and actuate the pointer.

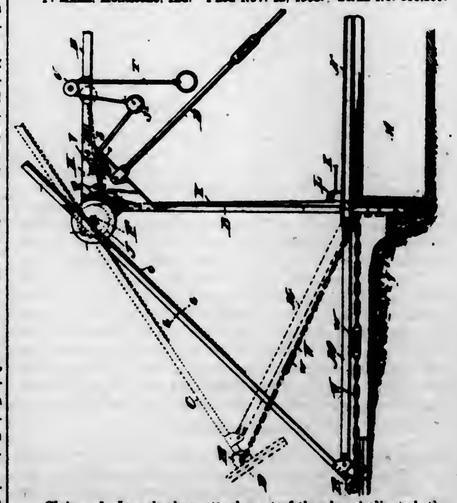
7. A device for measuring the thickness of paper comprising a frame, an indicator bearing scale-marks, a pointer coöperating with the scale-marks, a roller secured to the pointer, a second roller spaced from the pointer-roller, a rod passing between the rollers and in contact therewith, a cylinder in which the end of the rod operates, a reservoir containing fluid and communicating with the cylinder, a piston in the reservoir, and means for connecting the piston with a paper-treating machine, whereby the thickness of the paper being treated will cause the piston to force the fluid against the rod and actuate the pointer.

8. A device for measuring the thickness of paper, comprising a frame, an indicator bearing scale-marks, a pointer coöperating with the scale-marks, a roller connected to the pointer, a rod for operating mechanism between the roller and a calendering-machine for ing the roller, means for adjusting the roller in relation to the rod, imparting motion to said roller when paper is being treated.

9. A device for measuring the thickness of paper, comprising a frame, an indicator bearing scale-marks, a pointer coöperating with the scale-marks, a rod actuating the pointer, a weight carried by one end of the rod, a piston formed on the other end of the rod, a cylinder in which the piston operates, a reservoir containing liquid and communicating with the cylinder, a piston in the reservoir and spaced from the piston on the rod, a rod connected to the reservoir-piston, a yoke on the end of said rod, a weight connected to the yoke, and a pivoted lever fitting in the yoke.

10. A device for measuring the thickness of paper, comprising a frame, an indicator bearing scale-marks, a pointer coöperating with the scale-marks, a piston actuating the pointer, a cylinder in which the piston operates, a reservoir of larger area than the cylinder and containing fluid and communicating with the cylinder, a piston in the reservoir spaced from the cylinder, and means for connecting the piston to a paper-treating machine.

812,043. SIDE BRACE OR ANCHOR FOR DREDGERS. JAMES P. KARR, Monticello, Ind. Filed Nov. 12, 1903. Serial No. 180,869.



Claim.—1. In a dredger attachment of the class indicated, the combination with a scow or equivalent, and a frame thereon, of a

spud or brace, and means for guiding the same on the frame, a bar connecting it pivotally with the scow, and a platform which is pivotally connected with the lower end of the brace at a point nearer its

ing a bolt-retracting means, a locking device for said retracting means, operating means for said device, and operating means for

said base or mat, and one end thereof to be buried in the river-bank

oped or brace, and means for guiding the same on the frame, a bar connecting it pivotally with the scow, and a platform which is pivotally connected with the lower end of the brace at a point nearer the outer edge of the platform than the inner edge of the same, substantially as and for the purpose specified.

2. In a dredger attachment of the class indicated, the combination with the scow and a vertical frame thereon, of the inclined brace and a bar pivotally connecting its lower end with the scow, a platform having a socket for reception of the spherical end of the brace; and provided with lateral ears, and chains extending therefrom toward the ends of the scow and provided with turnbuckles, substantially as shown and described.

3. In a dredger attachment of the class indicated, the combination with a scow, a vertical frame, a rotatable shaft having a pinion and arranged in bearings on said frame, a brace constructed of metal and having side flanges or ribs, a rack arranged in the groove between said flanges, and a bar which pivotally connects the lower end of the brace with the scow, substantially as described.

4. In a dredger attachment of the class indicated, the combination with a scow or equivalent, and a vertical frame thereon, of a brace, a platform, and a bar which pivotally connects the lower end of the brace with the scow, of a shaft mounted in bearings on the upper portion of the frame, and provided with a pinion engaging the rack of the brace and with a winding-drum, and a hoisting-cable applied to the latter and extending downward to the deck of the scow, and means for locking the said shaft, substantially as described.

5. In a dredger attachment of the class indicated, the combination with a scow, and a frame fixed thereon, of a brace having a rack-bar, a platform, and a bar which pivotally connects the lower end of the brace with the scow, of a shaft which is journaled in the upper portion of said frame, and provided with a pinion engaging the rack of the brace, and a wheel provided with sockets, of a slidable bolt adapted to engage the said wheel, and means for moving the same into or out of engagement with the wheel, substantially as described.

6. In a dredger attachment of the class indicated, the combination with the scow, a frame fixed thereon, and a platform and brace, of a rotatable shaft having a pinion which engages the rack of the brace, and the wheel provided with sockets, a slidable locking-bolt adapted to engage said wheel, a pivoted lever and a link connecting it with the bolt, whereby the adjustment of the free end of the lever effects engagement and disengagement of the bolt with the wheel, substantially as described.

7. In a dredger attachment of the class indicated, the combination with a scow, a vertical frame, an inclined brace having a rack-bar, of a shaft journaled horizontally in said frame, and a pinion thereon which engages the rack, and a wheel provided with peripheral sockets, a slidable locking-bolt adapted to engage said sockets, a pivoted and weighted lever, and a link connecting it with the bolt, and a rope attached to the free end of the lever and serving to raise it, as and for the purpose specified.

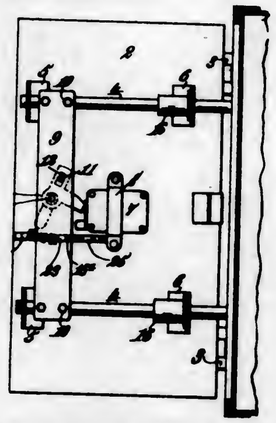
8. In a dredger attachment of the class indicated, the combination with the scow, and a vertical frame fixed thereon, of an inclined brace having a rack affixed, a rotatable shaft arranged horizontally on said frame and provided with a pinion which engages the rack and with a wheel having peripheral sockets which are undercut as described, of a slidable bolt having an enlarged head, and means for operating the same, substantially as described.

9. In a dredger attachment of the class indicated, the combination with the scow, and a frame fixed thereon, of an inclined brace having a rack affixed, a rotary shaft journaled horizontally in said frame and having a pinion which engages the rack, and a wheel provided with peripheral sockets which are undercut as described, a slidable bolt having an enlarged head adapted to enter said sockets, and keepers arranged adjacent to the wheel and adapted to engage a shoulder formed on the head of the bolt, substantially as described.

10. In a dredger attachment of the class indicated, the combination with the scow, a frame mounted thereon, an inclined brace having a rack-bar, a shaft journaled in said frame and having a pinion engaging the rack-bar, and a wheel provided with sockets, of a slidable bolt held in keepers on said frame, a pivoted weighted lever, and a link connecting it with the said bolt, and a stop-plate arranged on the frame for engagement with the inner end of the lever, for holding the bolt engaged with the wheel, substantially as described.

812,044. **BOLT OPERATING AND LOCKING MECHANISM.** WILLIAM J. KAMMERMAN, Buffalo, N. Y., assignor to Cary Safe Company, Buffalo, N. Y., a Corporation of New York. Filed Mar. 26, 1903. Serial No. 149,329.

Claim.—1. A bolt operating and locking mechanism comprising a bolt-retracting means, a locking device for said retracting means, operating means for said device, and operating means for said bolt-retracting means, said operating means for said device moving in an opposite direction with respect to the direction of movement of the operating means for the said bolt-retracting means, said bolt-retracting means when in its operative position engaging said locking means and retaining it from movement until the retracting means is moved to inoperative position, combined with one or more bolts connected to said retracting means and adapted to be moved in one direction by said means, and a casting means engaging said bolt or bolts for operating it or them in the opposite direction when said retracting means is released.



2. A bolt operating and locking mechanism comprising a bolt-retracting means, a locking device for said retracting means, a key for operating said device, and a handle for operating said bolt-retracting means, said key operating in a different direction with respect to the direction of movement of the said handle, said bolt-retracting means when in its operative position engaging said locking means and retaining it from movement until the retracting means is moved to inoperative position, combined with a bolt connected to said retracting means and adapted to be moved in one direction by said means, and a casting means engaging said bolt for operating it in the opposite direction when said retracting means is released.

3. A bolt operating and locking mechanism comprising a bolt-retracting means, a locking device for said retracting means, operating means for said device, and operating means for said bolt-retracting means, said operating means for said device moving in an opposite direction with respect to the direction of movement of the operating means for the said bolt-retracting means, combined with one or more bolts connected to said retracting means and adapted to be moved in one direction by said means, a casting means engaging said bolt or bolts for operating it or them in the opposite direction when said retracting means is released, and a trip device for releasing said retracting device.

4. A bolt operating and locking mechanism comprising a bolt-retracting means, a locking device for said retracting means, a key for operating said device, and a handle for operating said bolt-retracting means, said key operating in a different direction with respect to the direction of movement of the said handle, combined with one or more bolts connected to said retracting means and adapted to be moved in one direction by said means, a casting means engaging said bolt or bolts for operating it or them in the opposite direction when said retracting means is released, and a trip device for releasing said retracting device.

5. A bolt operating and locking mechanism comprising a bolt-retracting means, a locking device for said retracting means, operating means for said device, and operating means for said bolt-retracting means, said operating means for said device moving in an opposite direction with respect to the direction of movement of the operating means for the said bolt-retracting means, said bolt-retracting means when in its operative position engaging said locking means and retaining it from movement until the retracting means is moved to inoperative position, combined with one or more bolts connected to said retracting means and adapted to be moved in one direction by said means, a casting means engaging said bolt or bolts for operating it or them in the opposite direction when said retracting means is released, and a trip device for releasing said retracting device.

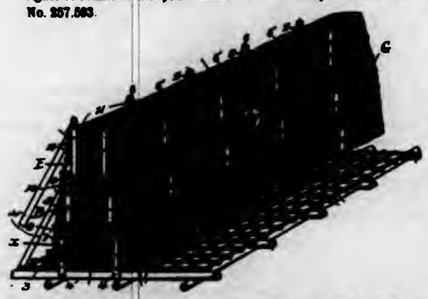
6. A bolt operating and locking mechanism comprising a bolt-retracting means, a locking device for said retracting means, a key for operating said device, and a handle for operating said bolt-retracting means, said key operating in a different direction with respect to the direction of movement of the said handle, said bolt-retracting means when in its operative position engaging said locking means and retaining it from movement until the retracting means is moved to inoperative position, combined with a bolt connected to said retracting means and adapted to be moved in one direction by said means, a casting means engaging said bolt for operating it in the opposite direction when said retracting means is released, and a trip device for releasing said retracting device.

7. A bolt operating and locking device comprising as a part thereof, a bolt-retracting means, said means comprising a bolt-carrying bar, a lug secured to said bar, a bell-crank having one of its arms slotted into which operates the said lug, a shaft having its inner end fixed to said bell-crank, a handle fixed to the outer end of said shaft, and a beveled lug carried by said bar, combined with a trip device engaging said beveled lug and acting as a means for retaining said retracting means in its operative position.

8. A bolt operating and locking device comprising as a part thereof means for simultaneously and automatically casting a plurality of bolts, said means comprising a barrel for each of the bolts, an expansion-spring arranged in the barrel and adapted to surround the bolts, combined with a bolt extending through each of the barrels and each having a protuberance engaging its respective spring for compressing it when the bolt is moved in one direction, a bar for connecting the bolts together, and a trip engaging the bar for arresting the movement thereof, thereby retaining the springs in a compressed position until the trip is released to permit of the automatic and simultaneous casting of the bolts.

9. A bolt operating and locking device comprising the combination with a bolt, of a retracting means connected with the bolt and adapted when operated to move the bolt in one direction, a casting means engaging the bolt and adapted to move it in an opposite direction, and a locking means for the retracting means when the bolt is cast, said retracting means when moved to operative position adapted to act as a retaining means for holding the locking means in an inoperative position.

812,045. **FASCINE.** HENRY F. KELLNER, North Platte, Nebr., assignor to Jennie Whitney, Fremont, Nebr. Filed Apr. 27, 1905. Serial No. 257,563.



Claim.—1. A fascine of permeable substance, built up of sections and having opposite ends projecting beyond the main body portion.

2. A fascine of permeable substance, consisting of a plurality of sections, and having projecting ends, in combination with a mat or base.

3. A fascine of permeable substance, consisting of a plurality of sections, the lower sections being secured to a mat or base, wire covering secured to each side of said sections and the top of said mat or base, and means for bracing said sections, substantially as described.

4. A fascine, comprising a wall of permeable substance protected by means of wire covering, and having opposite projecting ends in combination with a base or mat having the wire covering and provided with brace members to support aforesaid wall.

5. A fascine of the character described consisting of a base or mat provided with a wire covering, upright sections of permeable substances extending upward from said base or mat to form the permeable wall, said wall having opposite ends projecting beyond said base or mat, and one end thereof to be buried in the river-bank, and in combination with the shore-cables to help support and hold the fascine in place.

812,046. **SHELL-FUSE.** WILLIAM M. KINSHAW, Washington, D. C. Filed Nov. 11, 1904. Serial No. 232,341.

Claim.—1. In a shell-fuse, the combination with a suitable stock, of a normally restrained time mechanism, a fixed magazine, and means fired by the charge in the fixed magazine to release the time mechanism.

2. In a shell-fuse, the combination with a suitable stock of a normally restrained time mechanism, a fixed magazine, means fired by the charge in the fixed magazine to release the time mechanism, and means for regulating the speed of travel of said time mechanism.

3. In a shell-fuse, the combination with a suitable stock, of a fixed magazine, a normally restrained time mechanism, and an ejector for releasing said time mechanism.

4. In a shell-fuse, the combination with a suitable stock, of a fixed magazine, a normally restrained time mechanism, an ejector for releasing said time mechanism, and means for regulating the speed of travel of the time mechanism.

5. In a shell-fuse, the combination with a suitable stock, of a normally restrained time mechanism, a fixed magazine, means fired by the charge in the fixed magazine to release the time mechanism, and a valve for regulating the speed of travel of said time mechanism.

6. In a shell-fuse, the combination with a suitable stock, of a fixed magazine, a normally restrained time mechanism, an ejector for releasing said time mechanism, and a valve for regulating the speed of travel of the time mechanism.

7. In a shell-fuse, the combination with a suitable stock, of a fixed magazine, a normally restrained traveling magazine, means for releasing said traveling magazine, and means for causing the traveling magazine to move at a uniform rate of speed.

8. In a shell-fuse, the combination with a suitable stock, of a fixed magazine, a normally restrained traveling magazine, means for releasing said traveling magazine, and cup-washers or valves adapted to cause the traveling magazine to travel or move at a uniform rate of speed.

9. In a shell-fuse, the combination with a suitable stock, of a fixed magazine, a normally restrained traveling magazine, means for releasing said traveling magazine, and cup-washers or valves attached to the traveling magazine, and adapted to cause the same to move at a uniform rate of speed.

10. In a shell-fuse, the combination with a suitable stock, of a fixed magazine, a normally restrained traveling magazine, means for releasing said traveling magazine, cup-washers or valves adapted to cause the traveling magazine to move at a uniform rate of speed, and means for controlling the speed.

11. In a shell-fuse, the combination with a suitable stock, of a fixed magazine, a normally restrained traveling magazine, means for releasing said traveling magazine, cup-washers or valves swiveled to the traveling magazine, and an air-valve for controlling the speed of said traveling magazine.

12. In a time-fuse, the combination with a movable magazine, of an air-cushioning device, whereby the said magazine is caused to move at a uniform rate of speed.

13. In a time-fuse, the combination with a movable magazine, of an air-cushioning device, whereby the said magazine is caused to move at a uniform rate of speed, and means for controlling the speed.

14. In a time-fuse, the combination with a movable magazine, of an air-cushioning device adapted to cause said magazine to move at a uniform rate of speed, and an air-valve for regulating the escape of air to control the speed.

15. In a shell-fuse, the combination with a suitable stock, of a fixed magazine, a normally restrained traveling magazine, an ejector adapted to release said traveling magazine, and an air-cushioning device, adapted to cause the traveling magazine to move at a uniform rate of speed.

16. In a shell-fuse, the combination with a suitable stock, of a fixed magazine, a normally restrained traveling magazine, a powder-containing ejecter adapted to release said traveling magazine, an air-cushioning device, adapted to cause the traveling magazine to move at a uniform rate of speed, and a valve for controlling the speed.

17. In a time-fuse, the combination with a suitable stock, of a time mechanism composed of a spring-actuated traveling magazine having a locking-sleeve at one end and an air-cushioning device at the other end.

18. In a time-fuse, the combination with a suitable stock, of a spring-actuated traveling magazine having a locking-sleeve at one end and an air-cushioning device at the other end, and means for controlling the rate of speed of said traveling magazine.

19. In a shell-fuse, the combination with a suitable stock, of a normally restrained time mechanism, a fixed magazine, means fired by the charge in the fixed magazine to release said time mechanism, and a primer-chamber surrounding the air-cylinder.

20. In a shell-fuse, the combination with a suitable stock, of a normally restrained time mechanism, a fixed magazine, means fired by the charge in the fixed magazine to release said time mechanism, a cylinder inclosing the time mechanism, and a primer-chamber surrounding said cylinder and in communication therewith.

21. In a shell-fuse, the combination with a suitable stock, of a fixed magazine, a spring-actuated traveling magazine, adapted to be normally restrained, means for releasing said traveling magazine, means for causing the traveling magazine to move at a uniform rate of speed, a primer-chamber, and means for controlling the speed of said traveling magazine.

22. In a shell-fuse, the combination with a suitable stock, of a traveling magazine, a fixed magazine, and means fired by the charge in the fixed magazine to release the traveling magazine.

23. In a shell-fuse, the combination with a suitable stock, of a traveling magazine normally held against movement, and an ejector adapted to be fired by the charge in the fixed magazine to release the traveling magazine.

24. In a shell-fuse, the combination with a suitable stock, of a traveling magazine, an air-cushioning device carried by the traveling magazine, and means fired by the charge in the fixed magazine to release said traveling magazine.

25. In a shell-fuse, the combination with a suitable stock, of a traveling magazine, means for normally holding the traveling magazine against movement, a fixed magazine, means fired by the charge in the fixed magazine to release said holding means and release said traveling magazine.

26. In a shell-fuse, the combination with a suitable stock, of a traveling magazine, means for normally holding the traveling magazine against movement, a fixed magazine, an air-cushioning device attached to said traveling magazine, and means fired by the charge in the fixed magazine to release said holding means and thereby release the traveling magazine.

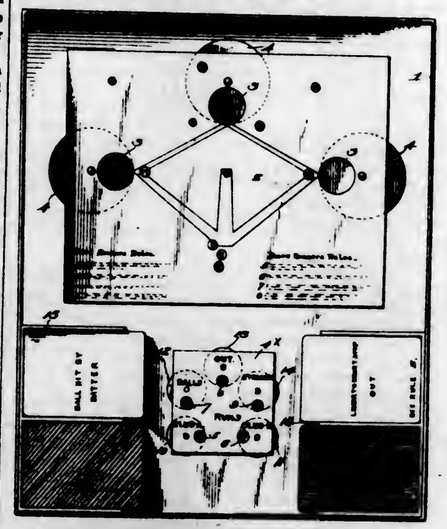
812,047. MATCH-BOX. ROBERT B. KING, Beaufort, N. C. Filed Sept. 9, 1905. Serial No. 277,726.

Claim.—1. A match-box having a magazine, and a contracted feed-channel below the same and provided with an outlet at one end thereof, the lower edges of the walls of the channel forming guide-flanges and having inturned portions adjacent to the rear end of the channel to constrict the same at that point, and a match-ejector having a scratch-surface and coacting guide-flanges and front and rear projections to, respectively, normally close the outlet and engage the end of a match to be fed forward, the outlet being of such size as to permit tilting of the match as it is withdrawn to permit the beaded end thereof to be manually pressed against said scratch-surface and ignited.

2. A match-box having a magazine and a contracted feed-channel below the same and provided with an outlet, the lower edges of the walls of the channel forming guide-flanges, and a match-ejector having coacting guide-flanges and front and rear projections to respectively normally close the outlet and engage the end of a match to be fed forward.

3. A match-box having a magazine and a contracted feed-channel below the same and provided with an outlet, the lower edges of the walls of the channel forming guide-flanges and having inturned portions adjacent to the rear end of the channel to constrict the same at that point, and a match-ejector having coacting guide-flanges and front and rear projections to respectively normally close the outlet and engage the end of a match to be fed forward.

812,048. GAME APPARATUS. GEORGE F. KIRBY, New Bedford, Mass. Filed May 16, 1904. Serial No. 208,217.



Claim.—1. A game-board having a representation of a base-ball field, openings at the bases of the field and a revoluble disk under each of said openings, said disks having symbols to indicate the base-runners at the bases during the progress of the game.

2. A game-board having a representation of a base-ball field, openings at the bases of the field, and movable devices having symbols and coacting with the said openings to display the symbols to indicate the base-runners at the bases during the progress of the game.

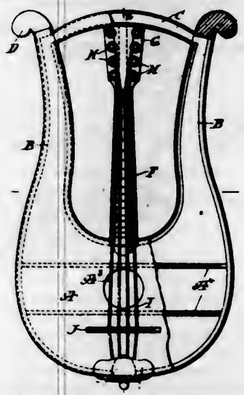
812,049. MUSICAL INSTRUMENT. ARAMUS M. KRUEGER, Bellville, Tex. Filed Dec. 22, 1904. Serial No. 238,606.

Claim.—1. A stringed musical instrument provided with a lyre-shaped hollow body having hollow side arms, and a hollow cross-bar connecting the ends of the side arms of the body with each other and communicating with the interior thereof.

2. A stringed musical instrument provided with a lyre-shaped hollow body having a hollow cross-bar connecting the ends of the side arms of the body with each other communicating with the interior of said side arms and a hollow neck and head connecting the body with the said cross-bar.

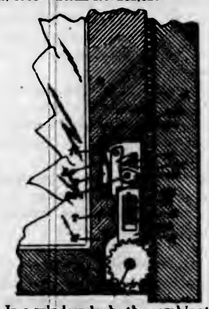
3. A stringed musical instrument comprising a body having hollow side arms and a hollow cross-bar connecting the side arms with each other and communicating with the interior of said side arms a hollow neck extending from the upper end of the body and in communication therewith, and a hollow head on the said neck, connected with the said cross-bar and in communication with the interior thereof.

4. A stringed musical instrument comprising a body having hollow side arms and a hollow cross-bar connecting the side arms with each other and in communication with the interior thereof a hollow neck extending from the upper end of the body and in communication therewith, a hollow head on the said neck, connected with the said cross-bar and establishing communication between the interior of the neck and the cross-bar and solid ornaments on the free ends of the side arms.



5. A stringed musical instrument provided with a lyre-shaped hollow body having a hollow, arched cross-bar, connecting the ends of the side arms of the body with each other and establishing communication between the said side arms.

812,050. WINDOW-LOCK. NICHOLAS A. KUKELER, Braddock, Pa. Filed Oct. 12, 1905. Serial No. 282,827.

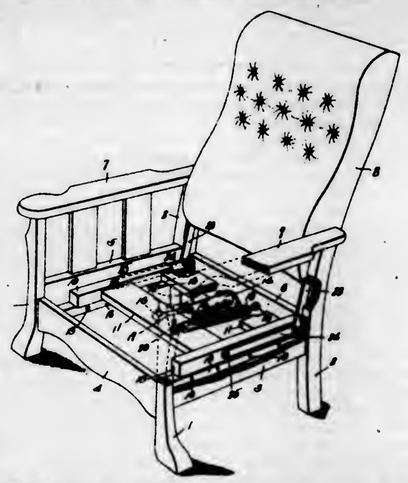


Claim.—1. In a window-lock, the combination with a window-frame and a sash slidably mounted therein, of a rack carried by said frame, said sash having recesses and a slot formed therein, a toothed wheel journaled in one of said recesses and adapted to engage said rack, a spring-pressed contact-block mounted in said slot and adapted to engage said toothed wheel, a spring-pressed latch mounted in the other of said recesses and adapted to engage said contact-block, a shaft journaled in said frame and a cam carried by said shaft and adapted when the shaft is rotated to engage said latch and said contact-block, substantially as described.

2. In a window-lock, the combination with a window-frame, and a sash slidably mounted therein, of a rack carried by said window-frame, a toothed wheel journaled in said sash and adapted to engage said rack, a spring-pressed contact-block slidably mounted in said sash and adapted to engage said toothed wheel, a spring-pressed latch adapted to engage said block and lock said block in engagement with said wheel, means actuated from the exterior of said sash to alternately move said latch and said contact-block, substantially as described.

812,051. RECLINING-CHAIR. HENRY J. LANAGAN, Clinton, Iowa. Filed July 24, 1905. Serial No. 271,208.

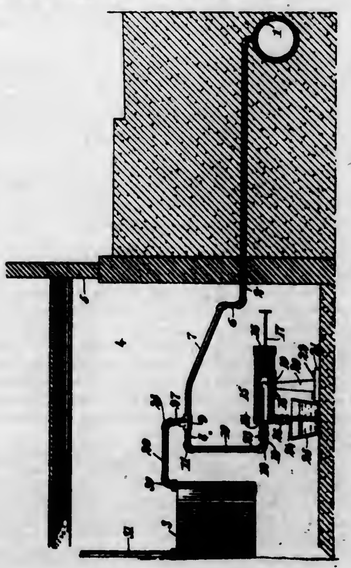
Claim.—1. The combination with the side members of a seat-frame adapted to support a seat, of guide-bars secured to the members, a sliding frame superposed upon the bars and disposed below the upper edges of the seat-frame, retracting and cushioning mechanisms operatively connected with the sliding frame, and a back pivotally connected with the seat-frame and with the sliding frame.



2. The combination with the side members of a seat-frame, of guide-bars secured to the inner sides thereof, a sliding frame mounted upon the bars and disposed below the upper edges of the side members, retracting and cushioning mechanisms operatively connected with the sliding frame, a back detachably combined with the seat-frame, links pivotally connected with the slide-bars, and arms rigid with the back and connected with the links.

3. In a chair, the combination with the rear legs having curved bearings, of a back having pintles to engage the bearings, a seat-frame adapted to support a seat, guide-bars secured to the inner faces of the seat-frame, a sliding frame mounted upon the guide-bars, and cushioning and retracting mechanisms connecting the seat-frame and the sliding frame.

812,052. LIQUID FORCING OR PUMPING DEVICE. LOUIS J. C. LARSEN, New York, N. Y., assignor of one-half to Adolph Rauh, New York, N. Y. Filed Aug. 7, 1905. Serial No. 273,075.



Claim.—In liquid-forcing devices of the character described, the combination with a service-pipe leading from a street gas-main to a house, of a pump provided with a suction-pipe and a discharge-pipe, a connection from said discharge-pipe to said service-pipe, and a branch leading from said connection to a meter.

812,053. WIRE-STAY. LYMAN G. LEACH, Wilton, Ohio, assignor of one-half to Charles A. Hinkley, Cleveland, Ohio. Filed May 20, 1905. Serial No. 261,295.

Claim.—1. A wire-stay consisting of a substantially U-shaped piece of metal having an opening formed therein, said piece of metal being bent to engage wires passing through said opening, substantially as described.

2. A wire-stay consisting of a piece of metal having an opening formed therein, said piece of metal being bent to engage wires passing through said opening.

3. A wire-stay consisting of a piece of metal having an opening formed therein, said piece of metal being bent to a substantially S shape to retain wires passing through said opening and the layers of metal formed by the bending of said piece, substantially as described.

4. A wire-stay consisting of a substantially S-shaped piece of metal, said piece of metal having openings formed therein through which wires are adapted to pass, substantially as described.

5. A wire-stay consisting of a piece of metal of substantially U shape, and having an opening intersecting the bend, and having an integral portion extending from below the said opening upwardly toward the same, said integral portion having its upper end notched to receive a wire extending through said opening.

812,054. ADJUSTABLE WAGON-BOX. MOSES LEHNART, Charlton, Iowa. Filed Sept. 6, 1905. Serial No. 277,231.

Claim.—1. In combination with a wagon-box, of a pair of separate supplemental frames superposed thereon, and means whereby these frames are locked down on the upper edge of the wagon-box or held above the same and separated from each other, substantially as set forth.

2. In combination with a wagon-box, of a pair of supplemental frames, and means for holding these frames on the upper edge of the wagon-box or elevated above the same and separated from each other, said means embodying vertical standards attached to the frames and having their lower ends working in sockets carried by the wagon-box.

3. In combination with a wagon-box provided with a series of stake-sockets pivotally mounted on the wagon-box, standards or stakes adapted to slide in these sockets and carrying a supplemental frame or box at their upper ends, and means for locking the standards in their raised position.

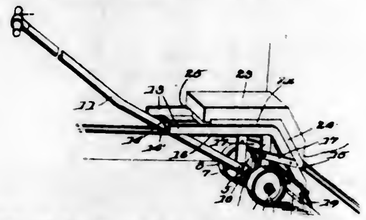
4. In combination with a wagon-box carrying a series of stake-sockets, each socket being pivoted at its upper end so as to swing forward and backward at its lower end, a stake working vertically in each socket and means for locking the stake in its elevated position, and a supplemental frame or frames supported on the stakes.

5. In combination with a wagon-box provided with a series of stake-sockets each pivoted at its upper end so that its lower end will have a forward and backward movement, a fastening device for the lower end of the socket, a supporting-stake working in each socket and means for locking it in its elevated position, and a supplemental frame or frames mounted on the stakes.

6. In combination with a wagon-box carrying a series of stake-sockets, each socket consisting of a plate provided with a vertical series of latch-receiving holes, a stake working vertically in each socket and carrying a spring-latch adapted to engage in one of said holes, and a supplemental frame or frames carried by the stakes, for the purpose set forth.

7. In combination with a wagon-box carrying a series of sockets, a stake working vertically in each socket and means for locking the stake in its elevated position, a top frame or rack attached to the stakes, an intermediate frame slidingly mounted on the stakes, and means for lifting and holding up the intermediate frame when the stakes are raised above a predetermined point, for the purpose set forth.

812,055. FLOOR-SCRAPER. STEPHEN A. M. LENVILLE, Concordia, Kans. Filed July 24, 1905. Serial No. 271,070.



Claim.—1. In a device of the class described, a wheeled truck, a weight-receiving platform carried by the truck and having one end thereof deflected downwardly, a pair of clamping members secured to the deflected end of the truck, and a scraping-tool interposed between the clamping members and adjustable laterally of the truck.

2. In a device of the class described, a wheeled truck provided with an operating-handle, a weight-receiving platform carried by the truck and having one end thereof secured to the operating-handle and its free end deflected downwardly, and a scraping-blade secured to the deflected end of the truck and adjustable laterally beyond the wheels of the latter.

3. In a device of the class described, a wheeled truck provided with an operating-handle, a horizontally-disposed weight-receiving platform carried by the truck and having one end thereof secured to the operating-handle and its free end deflected downwardly, and a scraping-blade carried by the deflected end of the platform, said blade being movable into and out of contact with the work by the movement of the operating-handle.

4. In a device of the class described, a wheeled truck, a supporting-frame mounted on the axle of the truck, a pair of spaced angle-irons secured to the supporting-frame and forming a weight-receiving platform, and a scraping-blade carried by the truck and adjustable laterally beyond the wheels thereof.

5. In a device of the class described, a wheeled truck, a weight-receiving platform secured to the truck and having its free end deflected downwardly, and a scraping-tool secured to the deflected end of said platform and adjustable laterally beyond the wheels of the truck.

6. In a device of the class described, a truck, a weight-receiving platform secured to the truck and having its free end deflected downwardly, a scraping-tool secured to the deflected end of the platform and adjustable laterally of the truck, a plurality of weights mounted on the platform, and means for preventing accidental displacement of said weight.

7. In a device of the class described, a wheeled truck, a weight-receiving platform mounted on the truck and having its free end deflected downwardly toward the wheels thereof, a bar extending transversely of the platform at the free end of the latter, a scraping-tool secured to said platform, and a weight provided with an angular extension for engagement with the transverse bar of the platform.

8. In a device of the class described, a truck, a weight-receiving platform mounted on the truck and having one end thereof deflected downwardly, a scraping-tool secured to the deflected end of the platform, a weight mounted on said platform and having one end thereof inclined or beveled.

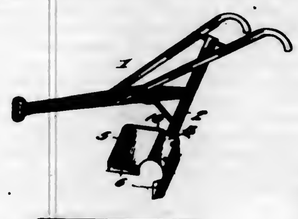
812,056. PLOW. CHARLES H. LITTLE, Chicago, Ill. Filed Aug. 11, 1905. Serial No. 273,830.

Claim.—1. A plow-shovel comprising a body portion, and a pair of upright outwardly-disposed blades provided with sharpened and inwardly-turned lower cutting edges.

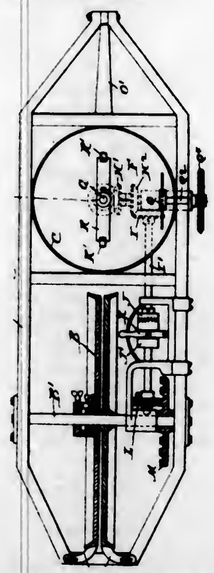
2. A plow-shovel comprising a body portion and forwardly-projecting angularly-disposed blades having at their lower edges inwardly-turned sharpened cutting portions.

3. A plow-shovel comprising a body portion, and angularly-disposed blades having at their lower edges inwardly-turned sharpened cutting portions and a vertical recess formed between the blades.

4. A plow-shovel formed in a single piece and comprising a central body portion, and oppositely-disposed forwardly-extending blades provided at their lower edges with inwardly-turned sharpened cutting portions.



812,057. SEED-PLANTER. JOSEPH W. LITTLE, Westpoint, Miss. Filed June 13, 1905. Serial No. 265,011.



Claim.—1. In a seed-planter, a suitable framework, a furrow-opener arranged at the forward end of the machine, a bed-plate secured in the forward portion of the framework, a feed-tube depending from the bed-plate, a covering-wheel arranged at the rear of the machine directly behind the feed-tube, a seed-hopper arranged above the bed-plate, a vertical shaft extending upward through the center of the bed-plate, mechanism for communicating power from the covering-wheel to this vertical shaft, means for varying the speed of said shaft, a clutch for throwing said shaft in or out of actionwhile the machine is traveling, an annular channel opening upward formed in the bed-plate, a feed-plate arranged above the bed-plate and removably secured to the central vertical shaft, a plurality of scrapers or wings carried by said feed-plate and adapted to travel within the annular channel, the annular channel provided with an opening extending through the bed-plate directly above the feed-tube, the feed-plate provided with a plurality of openings formed through the same, the bed-plate provided with a second opening located directly over the feed-tube, the openings of the feed-plate adapted to pass over said last-named opening of the bed-plate, a plate forming the bottom of the hopper arranged over the feed-plate and secured to the bed-plate, said plate being provided with an opening directly above the annular channel and also an opening under which the openings of the feed-plate will pass, both of said openings being out of register with the openings of the bed-plate connecting with the feed-tube, and means for closing either one of the openings through the upper plate, as and for the purpose specified.

2. In a seed-planter, a framework, a bed-plate secured to the framework near the forward end thereof, a furrow-opener arranged at the forward end of the machine, a feed-tube depending from the bed-plate and communicating with the rearward end of the furrow-opener, a covering-wheel journaled at the rear of the framework directly behind the feed-tube, a gear-wheel secured upon the same shaft as the covering-wheel, the face of said gear-wheel being provided with a series of different-size miter-gears, a seed-hopper arranged over the bed-plate, a central vertical shaft journaled in the bed-plate and extending below the same, a rearward-extending shaft, a movable miter-gear secured to the rear end of this shaft and adapted to be placed in the mesh with other of the miter-gears upon the differential gear, a train of gears adapted to transmit movement from the rearwardly-extending shaft to the vertical shaft in the hopper, the rearwardly-extending shaft being composed of two parts, a clutch, one member of which is secured to one half of the shaft, the other member being feathered upon the other half of the shaft, a lever for moving the slidable member in or out of clutch with the fixed member, an annular channel opening upward formed in the bed-plate, said annular channel being provided with an opening through the bed-plate above the feed-tube, a feed-plate removably secured to the vertical shaft, a series of wings or scrapers extending outward radially from said feed-plate and adapted to revolve within the channel, the feed-plate being provided with a series of openings formed through the same, the bed-plate being provided with an opening located over the feed-tube over which the openings of the feed-plate are adapted to pass as the plate revolves, a plate arranged above the feed-plate and removably secured to the bed-plate, this plate forming also the bottom of the hopper, said top plate being provided with an opening located directly above the annular channel, and also an opening under which the openings of the feed-plate will pass, both of said openings being out of alinement with the openings through the bed-plate, movable plates arranged above the top plate for the closing of either of the openings in the top plate, or for decreasing the size of said openings, a wheel journaled within the hopper, said wheel provided with a series of arms radiating from the same, said arms adapted to revolve so that the ends extend into the openings in the top plate directly over the channel, means for revolving this wheel from the power-shaft, and an agitator adapted to revolve within the hopper, as and for the purpose specified.

812,058. BOTTLE-STOPPER. WILLIAM F. MAHONY, Washington, D. C. Filed May 1, 1905. Serial No. 258,204.

Claim.—1. A bottle-stopper comprising a body portion, and a pull-tab projecting from the circumferential edge thereof, said tab having an aperture formed therein to receive the thumb or finger nail.

2. A bottle-stopper comprising a body portion, and a projecting pull-tab formed integral with said body portion and having an aperture therein to receive the thumb or finger nail.

3. A bottle-stopper comprising a body portion, and a pull-tab projecting from the circumferential edge thereof and having an aperture formed therein, the inner margin of said tab-aperture coinciding with the circumferential edge of said stopper.

4. A bottle-stopper comprising a body portion and a substantially U-shaped tab projecting from the circumferential edge thereof.

5. A bottle-stopper comprising a body portion, and a substantially U-shaped tab formed integral with said body portion and projecting from the circumferential edge thereof.

6. A bottle-stopper comprising a body portion, an integral pull-tab projecting from the circumferential edge of said body portion and having an aperture therein, the marginal edges of the stopper and tab-aperture being formed on curved lines and without abrupt angles, whereby the tendency of the parts to tear is eliminated or reduced.

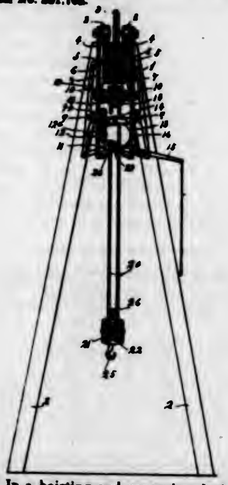
812,059. RAIL-JOINT. UMBERTO G. MARCUCCI, East Oakland, Cal. Filed Jan. 28, 1905. Serial No. 243,073.

Claim.—1. In a rail-joint, the combination of two adjacent rails, an angular fish-plate comprising separable vertical and horizontal members, and nuts and bolts for securing the fish-plate in applied position, the horizontal member of said fish-plate engaging said nuts to lock them in applied position.

2. In a rail-joint, the combination of two adjacent rails, an angular fish-plate comprising separable vertical and horizontal members, the meeting edges of said members being beveled in reverse directions, and nuts and bolts adapted to secure the fish-plate in applied position, the horizontal member of said fish-plate engaging the nuts to lock them in applied position.

3. In a rail-joint, the combination of two adjacent rails, a base-chair provided on its under side with transversely and longitudinally strengthening ribs, fish-plates; one of said fish-plates comprising separable vertical and horizontal members, and nuts and bolts for securing the fish-plates in applied position, the separable horizontal member of said fish-plate engaging said nuts to lock them in applied position.

812,060. **HAY ELEVATOR AND CONVEYER.** ADOLPH MELLQUIST and OSCAR A. WESTERSON, Cannon Falls, Minn. Filed March 23, 1905. Serial No. 251,702.



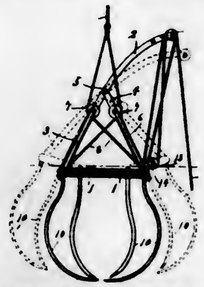
Claim.—1. In a hoisting and conveying device, the combination with a track having a series of lock depressions and a truck movable over said track, of a hoisting device applied to said truck, a lock mounted on said truck, and engageable with said lock depressions on the track, to lock said truck thereto, a latch for securing said hoisting device, with its load elevated, and connections thereby, said lock and said latch are thrown into and out of action in alternative order, substantially as described.

2. The combination with an elevated track having a series of lock depressions and a truck movable thereon, of a "block-and-tackle" hoisting device, applied to said truck, a pair of lock-levers, pivoted to said truck-frame and engageable on the opposite sides of said track, with said lock depressions to lock said truck thereto, a latch-hook, engageable with the movable block of said hoisting device, to lock the same in an elevated position, and connections whereby said movable block, on reaching its elevated position, releases said lock-levers from said lock depressions and throws said latch-hook into action upon itself, substantially as described.

3. The combination with an elevated track and a truck movable thereon, said track having alined recesses in its opposite sides, of the lock-levers 10, pivoted to the sides of the truck-frame and engageable with the lock-recesses of said track, a toggle, connecting the lower ends of said lock-levers, a latch-hook pivoted to the truck-frame and connected to said toggle, and a "block-and-tackle" hoisting device, having a movable block provided with a perforated head, arranged to set upon said toggle, to render said latch-levers inoperative and adapted to be engaged by latch-hook, substantially as described.

4. The combination with an elevated track, having in its sides lock-recesses 5, of a truck made up of a frame 7, and wheels 8, said frame embracing said track and said wheels running thereon, the latch-levers 10 pivoted to the sides of said frame and engageable with said lock-recesses 5, a toggle 11, connecting the lower ends of said levers, the latch-hook 13, pivoted to said frame and connected to said toggle, by a sliding link 12, the perforated aliming-plate 28, at the lower portion of said frame, the lever 15, pivoted to said frame and attached to said latch-hook, the sheaves 18, mounted on the said truck-frame, above said aliming-plate, the tackle-block 22, having the perforated head 26 and sheaves 21, and the cable 20, working over said sheaves 18 and 21, the perforated head 26, of which tackle-block is adapted to project through one of the perforations of said aliming-plate into engagement with said toggle 11 and adapted to be engaged by said latch-hook 13, substantially as described.

812,061. **GRAPPLE-FORK.** ADOLPH MELLQUIST and OSCAR A WESTERSON, Cannon Falls, Minn. Filed Mar. 23, 1905. Serial No. 251,703.



Claim.—1. The combination with a pair of scoops, a long arm rigidly secured to one thereof, and a short arm, rigidly secured to the other thereof, the said two arms being pivotally connected, of suspending cables arranged to cause scoops to close onto the load, under the action of gravity, and a cable connection between the upper end of said long arm and one of the scoop portions, for opening the scoops, substantially as described.

2. The combination with a pair of scoops, of a long arm rigidly secured to one thereof, a short arm rigidly secured to the other thereof, said short arm being pivoted to the intermediate portion of said long arm, a sheave on the upper end of the said long arm, a sheave connected to the lower end of said short arm, a cable running over said two sheaves and arranged to separate said scoop-sections, other sheaves on said two arms, and crossed cables attached to said scoops, passed over said latter-noted sheaves and connected at their upper end, said suspended cables operating to close the scoops under the action of gravity, substantially as described.

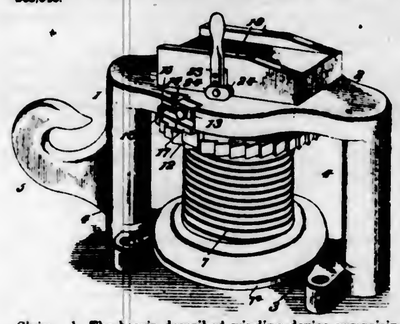
812,062. **BARREL.** JOHN T. MILLIGAN and JOSHUA D. MARVIL, Laurel, Del., assignors to Collapsible Barrel Company, Laurel, Del., a Corporation of Delaware. Filed Feb. 28, 1905. Serial No. 247,726.

Claim.—1. A barrel having a chime, a head composed of a plurality of parts to fit in said chime, and a wedge-like filling-piece to fit between one of the parts of the head and the body of the barrel, and having a notch to receive said head part the side edges of the latter being in parallelism.

2. A barrel having a chime, a head composed of a plurality of parts to fit in said chime, and a wedge-like filling-piece to fit between one of the parts of the head and the body of the barrel, and having a notch to receive said head part, the side edges of the latter being in parallelism and also having a projection to fit into said chime.

3. A barrel having a head composed of at least three parts, the barrel having a chime to receive the head, the side edges of the intermediate part of the head being in parallelism, and a wedge-like filling-piece to be driven longitudinally of the barrel into the space between one end of the said intermediate head-piece and the body of the barrel.

812,063. **WINDING MECHANISM FOR STUMP-EXTRACTORS.** GEORGE B. MERCHANT, Johnston, S. C. Filed May 31, 1905. Serial No. 263,046.



Claim.—1. The herein-described winding device comprising a drum for a cable having a spiral groove formed thereon, a sectional shell also having a spiral groove and designed to fit on and inclose said drum for regulating the diameter thereof, said shell being formed to fit in the grooves of the drum, means for holding such shell to the drum, and means for actuating the latter.

2. The herein-described winding device comprising a frame, a drum mounted therein having a ratchet-wheel at one end, a pawl or catch mounted on said frame for engaging said ratchet-wheel, a plate-spring affixed to the frame and designed to engage said pawl at either of two points, according as the pawl is in or out of engagement with said ratchet-wheel, and means for actuating the drum.

3. The herein-described winding device comprising a frame, a drum mounted therein having a ratchet-wheel at one end, a pawl or catch mounted on said frame for engaging said ratchet-wheel and having an overhanging flange, a plate-spring engaging said pawl for holding it in engagement with said ratchet-wheel, said plate-spring being capable of engaging said flange for holding the pawl out of engagement with said ratchet-wheel, and means for actuating the drum.

4. The combination with the frame having top and bottom members, of the drum rotatably mounted between said members, means mounted on the top member for preventing accidental unwinding of the drum, the sweep-bar casting located above said member, capable of being moved vertically, means for normally interlocking said casting with the drum when the former is in its lowermost position, and means mounted on said casting and engaging said top member for disengaging said casting from the drum.

5. The combination with the frame, of the drum rotatably mounted therein, means for preventing the accidental unwinding of the drum, the shaft with which said drum rotates, the sweep-bar casting, means for normally interlocking said casting to said shaft, and a lever for disengaging the sweep-bar casting from the shaft.

6. The combination with the frame, of the shaft mounted therein having a rounded portion fitting in an opening of the frame and also having a squared portion, the drum having at one end a squared chamber to accommodate said squared portion, means for preventing the accidental unwinding of the drum, the sweep-bar casting mounted above said frame and designed to interlock with said shaft, and means for disengaging said casting from the shaft.

7. The combination with the frame, of the shaft mounted therein having a rounded portion fitting in an opening of the frame and also having a squared portion, the drum having at one end a squared chamber to accommodate said squared portion, means for preventing the accidental unwinding of the drum, the sweep-bar casting mounted above said frame and designed to interlock with said shaft, and a lever mounted on said casting having cam-like or rounded portions for engaging said frame for disengaging the casting from said shaft.

8. The combination with the frame, and the shaft, of the drum movable with said shaft, the sweep-bar casting, means for interlocking the latter with said shaft, means for disengaging such casting, and a crank for turning said shaft and drum independently of the casting.

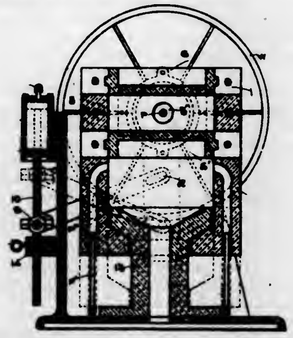
812,064. **CIGAR RETAINER AND CUTTER.** SAMUEL P. MILLER, Boston, Mass. Filed Mar. 27, 1905. Serial No. 252,173.

Claim.—1. In an article as described, the combination of a cylindrical body open at the end, bayonet-slots in one end thereof, and a second cylinder closed at one end and having studs thereon adapted to coöperate with the aforesaid bayonet-slots by which means the two cylindrical portions may be detachably interlocked.

2. In a device as described, a cylindrical body portion open at both ends, and bayonet-slots in one end thereof, a second cylindrical body closed at one end and having studs adapted to coöperate with the aforesaid bayonet-slots, a diaphragm mounted within said first-named cylindrical portion and a spiral spring inclosed between the said diaphragm and the said second cylindrical body whereby the two cylindrical bodies are held in separable interlocked relation.

3. In a device as described, a cylindrical body having a hole in one side thereof for the insertion of a cigar-tip, and bayonet-slots in one end thereof, a diaphragm within said cylindrical body, a second cylindrical body adapted to be slidably mounted within said first-named cylindrical body and having studs on one end thereof adapted to engage the aforesaid bayonet-slots and thereby to hold the two cylindrical bodies in separable interlocked relation and a spiral spring interposed between the aforesaid diaphragm and the second cylindrical body, the inner end of the said second cylindrical body constituting a cutting-blade by which the ends of the cigar when inserted in the hole aforesaid may be cut off.

812,065. **GLASS-WORKING FURNACE.** IRA A. MILLIRON, Franklin, Pa. Filed Aug. 1, 1905. Serial No. 272,177.



Claim.—1. A glass-working furnace having a central heat-chamber, glass-receptacles located upon opposite sides of said chamber with their bottoms in juxtaposition, and means of revolving said furnace.

2. A vertically-revoluble glass-working furnace having an inclosed heat-chamber with means of admitting heat thereto, said chamber having glass-receptacles located upon opposite sides thereof with their openings facing outward.

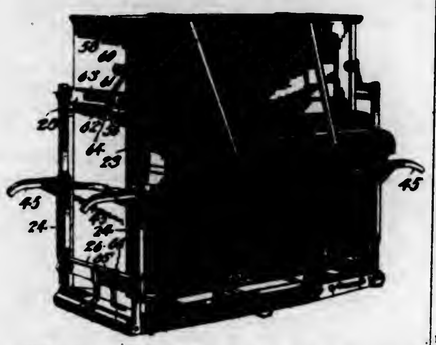
3. A glass-working furnace having glass-receptacles in its top and bottom sides, a heat-chamber located between said receptacles, means of generating heat in said chamber, in combination with means of revolving said furnace, and means of generating heat beneath the same.

4. A vertically-revoluble glass-working furnace having a plurality of glass-receptacles located in the walls thereof, and means of generating heat between said receptacles.

5. The combination with a revoluble furnace having a central heat-chamber and the glass-receptacles located at opposite sides thereof, of means of generating supplementary heat beneath said furnace, means of revolving said furnace and means of preventing the revolving of said furnace.

6. A revoluble glass-working furnace having an interior heat-chamber the glass-receptacles located in the walls of said chamber, in combination with a supplementary furnace, means of bringing said supplementary furnace into proximity to said first-mentioned furnace and of removing the same therefrom.

812,066. **TRUCK.** HENRY W. MOORE, Anderson, Ind., assignor of one-fifth to Mattie G. Moore, Madison county, Ind. Filed Feb. 4, 1905. Serial No. 244,227.



Claim.—1. In a truck of the character described, the combination of a base-frame, upright end frames, extension-arms on the upright end frames adjustably engaging the base-frame, automatic locking devices on the base-frame for fastening the extension-arms thereto, and means for simultaneously retracting said locking devices.

2. In a truck of the character described, the combination of a base-frame provided with guides, upright end frames, rack-bars on the end frames slidable in said guides, dogs within the guides for engaging said rack-bars, and means for retracting said dogs from the exterior of the guides.

3. In a truck of the character described, the combination of a base-frame provided with guides, upright end frames, rack-bars on the end frames slidable in said guides, automatic dogs within the guides for adjustably locking said rack-bars to the base-frame, and means for simultaneously releasing the dogs of each end frame.

4. In a truck of the character described, the combination of a base-frame, upright end frames extension-arms on the upright end frames slidably engaging guides on the base-frame, automatic locking devices on the base-frame to lock the arms thereto, and means for retracting said device from the exterior of the base-frame.

5. In a truck of the character described, the combination of a base-frame, upright end frames, extension-arms on the upright end frames engaging the base-frame, said arms being provided with rack-teeth, dogs upon the base-frame to engage the rack-teeth, and operating devices for raising the dogs to disengage them from said teeth.

6. In a truck, the combination of a main frame provided with guides and having a central seating portion arranged below the plane of its ends, upright end frames having members slidably secured in said guides, rollers upon the top and bottom portions of each end frame, rollers at the center of the main frame, and means for lowering the central rollers so that the main frame may be tilted in either direction to run upon the central rollers and base-rollers of one of the end frames and to raise them so that the main frame will rest upon its said central seating portion and the rollers of both end frames, substantially as described.

7. A truck having central rollers and end rollers, adjustable brackets carrying the central rollers, bolts for locking said brackets in their adjusted positions, and means for simultaneously projecting and retracting the bolts.

8. A truck having central rollers and end rollers, brackets carrying the central rollers, said brackets being adjustably mounted, bolts for holding the brackets in their adjusted positions, a device controlling the action of both bolts, and means for operating said device from either or both sides of the truck.

9. A truck having central rollers and end rollers, adjustable brackets carrying the central rollers, spring-actuated bolts for securing said brackets in their adjusted positions, a device for simultaneously retracting the bolts, and means for operating said device from either side of the truck.

10. In a truck, the combination of a base-frame, upright end frames adjustably connected with the base-frame, and angular supporting-brackets pivotally mounted upon the end frames and adapted to be projected inwardly from said frames to serve as supplementary supports.

11. A truck comprising a base-frame, upright end frames adjustably secured thereto, each of said frames having slotted stems, handles pivotally mounted within the slotted standards, locking-pins upon the handles, and slotted links receiving said pins and pivotally connected within the slots of the standards, the slots of the links being formed with a series of receiving-notches to receive the locking-pins whereby the handles may be adjusted and locked at different angles and folded substantially parallel with the end frames.

12. A truck having supporting-rollers provided with sets of ratchet-teeth projecting in opposite directions, and a reversible locking-pawl adapted to engage either set of teeth to hold the roller against retrograde movement in either direction.

13. A truck having supporting-rollers provided with oppositely-projecting sets of ratchet-teeth, pawls reversible to engage either set of teeth, guides and operating devices for the pawls, and means for locking the pawls to the guides in either of their adjusted positions.

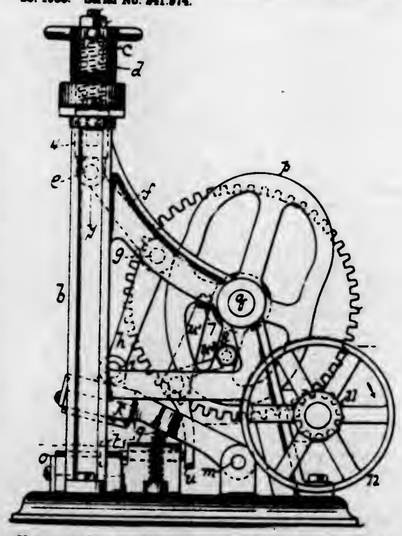
812,067. **TOOL.** DE HAVEN MORRIS, Wilmington, Del. Filed May 31, 1904. Serial No. 210,209.

Claim.—1. In a tool of the character stated, a head, a handle-receiving eye, the blade-end walls of which are divided, independent arms extending outwardly from said walls, said walls and arms being primarily spread apart and of resilient nature a handle, a blade within said arms and secured thereto, a spur on an inner side wall of said eye adapted to engage said handle and an additional fastening device for said handle consisting of a pin passing through a side wall of said eye and through said handle and clenched on the latter.

2. In a tool of the character stated, a head, an eye therein, a handle in said eye, an opening in a side wall of said eye, and a pin passing through said opening and through said handle and having its inner end deflected on an opposite imperforate portion of said eye and clenched on said handle.

3. A tool of the character stated consisting of a head, an eye therein, a handle in said eye, an opening in a side wall of said eye, the portion of the other wall opposite to said opening being imperforate and a pin passing through said opening and handle and having its inner end deflected on the imperforate portion and clenched on said handle.

812,068. **BOTTLE-CAPPING MACHINE.** HERMAN MÜLLER, Astoria, and EUGENE ZIPPRICH, New York, N. Y., assignors to Budde & Westermann, New York, N. Y., a Corporation of New York. Filed Jan. 20, 1905. Serial No. 241,874.



Claim.—1. In a machine for capping bottles and the like a pair of jaws and a jaw-actuating means comprising a cam with actuating portions of unequal height separated by low or inactive portions.

2. In a machine for capping bottles and the like the combination with jaws of a jaw-actuating cam having actuating portions of varying eccentricity with low or inactive portions therebetween to variously actuate or compress the jaws and open or release the same a number of times during one rotation of the cam.

3. In a machine for capping bottles and the like the combination with a stationary jaw, a movable jaw, and an actuating-cam and suitable connections for conveying motion from the cam to the movable jaw, said cam having unequal jaw or actuating parts with intermediate low or releasing parts.

4. In a machine for capping bottles and the like, the combination with jaws and actuating means thereof, of a clutch and clutch engaging and releasing means actuated by the bottles and the actuating means for respectively engaging and releasing the clutch.

5. In a capping-machine the combination with jaws and jaw-actuating means of a clutch, a lever for the clutch, a stud on the actuating means and a slide at the jaws said stud and slide being made to actuate the lever to release and engage the clutch.

6. A pair of jaws and an actuating-cam for one of the jaws, a driver or pulley for the cam, a clutch for connecting the driver and the cam, a lever for freeing or uncoupling the clutch and allowing it to engage, a stud on the cam to actuate the lever for uncoupling the clutch, and a slide in the jaws in the path of a bottle introduced therebetween and actuated thereby for setting the lever to allow the clutch to couple or engage.

7. A pair of bottle-capping jaws, an actuating-cam therefor, a pulley or driver, a clutch for connecting the driver and cam, a releasing-arm for the clutch, a lever for setting the arm, a stud on the cam for setting the lever one way, and a slide at the jaws actuated by an inserted bottle to set the lever in the opposite direction.

8. A capping-machine having a jaw-actuating toggle-joint and a cam made to act against the links of the joint to straighten the same.

9. A capping-machine having jaws, a toggle-joint having one link connected to the jaws, a bearing-point for the other link and a cam made to engage the links to compress the jaws.

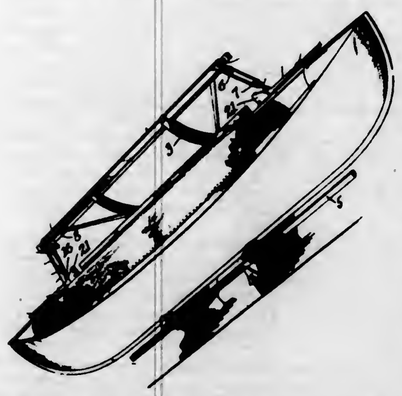
10. A capping-machine having jaws, an actuating toggle-joint therefor, and a spring-pressed or yielding bearing-pivot for the toggle-joint.

11. A capping-machine having jaws, an actuating toggle-joint therefor, a bearing or pivot for one link of the toggle-joint, an adjustable stem for the pivot, a spring made to act on the stem, and an adjustable cap or thimble for supporting the stem.

12. A capping-machine having jaws and an actuating toggle-joint therefor, a bearing or pivot for the toggle-joint and provided with a stem, an adjustable thimble in which the stem is adjustable, and a spring for the stem.

13. A capping-machine having jaws and jaw-actuating means, and a bottle-actuated slide for bringing the actuating means into operation, said slide being composed of adjustable sections for lengthening or shortening the same.

812,069. **ATTACHMENT FOR BOAT-DAVITS.** NEIL MURCHISON, New York, N. Y. Filed Feb. 1, 1905. Serial No. 243,654.



Claim.—1. The combination of a pair of connected davits each having a curved portion to support and overhang a boat, means for suspending one end of the boat from each of said curved portions, means for rocking the davits to swing the boat into and out of them, and means for simultaneously operating both of said suspending means.

2. The combination of a pair of connected davits each having a curved portion to support and overhang a boat, means for suspending one end of the boat from each of said curved portions, means for rocking the davits to swing the boat into and out of them, means for simultaneously operating both of said suspending means, and additional means for lifting the boat out of the chocks of the davits.

3. The combination of a pair of connected davits each having a curved portion to support and overhang a boat, means for suspending one end of the boat from each of said curved portions, means for rocking the davits to swing the boat into and out of them, means for simultaneously operating both of said suspending means, and additional means for lifting the boat out of the chocks of the davits; said last-named means comprising a lever fulcrumed to the suspending means and connected with the boat.

4. The combination of a pair of connected davits each having a curved portion to support and overhang a boat, means for suspending one end of the boat from each of said curved portions, means for rocking the davits to swing the boat into and out of them, means for simultaneously operating both of said suspending means, additional means for lifting the boat out of the chocks of the davits, and means for securing said last-mentioned means in position to hold the boat on said supporting means.

5. The combination with a boat-davit, of means for lifting a boat therefrom, and means for thereafter lowering the boat and the lifting means.

6. The combination with a boat-davit, of means for lifting a boat to free it therefrom, means for securing the lifting means in a stationary position on the boat, and additional means for thereafter raising or lowering the boat with the lifting means.

7. The combination with a boat-davit, of means for suspending a boat therefrom, and means pivotally mounted on the boat for steadying the boat with respect to the davit.

8. The combination with a boat-davit, of means for suspending a boat therefrom, and means for steadying the boat with respect to the davit; said steadying means comprising a lever for lifting the boat.

9. The combination with a boat-davit, of means for suspending a boat therefrom, and means for steadying the boat with respect to the davit; said steadying means comprising a lever for lifting the boat, and means for securing the lever in two different positions.

10. The combination with a boat-davit having chocks, of a boat adapted to be supported in the chocks, two levers for lifting the ends of the boat from the chocks, and additional means for simultaneously lowering the ends of the boat.

11. The combination with a boat-davit having chocks for supporting a boat, of a pair of falls and tackle each connected with one end of the boat, means for operating both sets of tackle simultaneously, and two levers for lifting the ends of the boat from the chocks.

12. The combination of a boat-davit having a top plate, a fall and tackle connected with the top plate, a lever connected with the running-block of the tackle and pivotally connected with the boat, means for securing the lever to the top plate, and means for securing the lever to the boat.

13. The combination of a boat-davit having a top plate, a fall and tackle connected with the top plate, and a lever fulcrumed to the running-block of the tackle and having a variable pivotal connection with the boat.

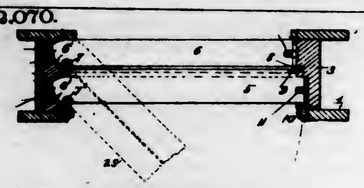
14. The combination of a pair of tackles, a fall connected with each tackle, means for connecting the running-blocks of both tackles with the boat, and means for simultaneously winding up the falls.

15. The combination of two sets of tackles each one being provided with a fall, means for simultaneously winding up said falls, and means for connecting the running-blocks of both tackles with the boat, said means comprising a pair of levers one fulcrumed to each of the running-blocks, said levers being pivotally connected with the boat.

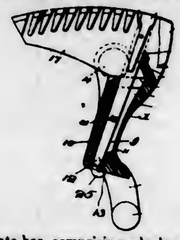
812,070. **REVERSIBLE WINDOW.** STANLEY MCAFEE, North Adams, Mass. Filed Nov. 3, 1904. Serial No. 231,217.

Claim.—The combination, with a window-casing, provided with removable sections for detaching and removing the sash-weights, and rounded bearings for the sashes at one side, of the window-sash having a rounded form at one side to cooperate with said rounded bearings, middle and facing beads adapted at one side for the sashes to turn thereon as pivots, and means for securing and releasing the sashes at the side opposite to that first mentioned.

812,070.



812,071. **SECTIONAL GRATE-BAR.** WILLIAM MCCLAVE, Scranton, Pa., assignor to McClave-Brooks Company, a Corporation of Pennsylvania. Filed Nov. 3, 1904. Serial No. 231,260.



Claim.—1. A grate-bar, comprising a body portion and removable caps provided with cutting edges, the body portion having walls of unequal heights, the higher wall engaging the caps at points opposite the cutting edges thereof with respect to the axis of the grate-bar and offering an abutment of great strength to them when the bar is rocked to cut out ashes and clinkers.

2. A grate-bar, comprising a body portion provided with sockets and caps provided with socket-engaging portions, said sockets flaring upwardly and downwardly from the central parts thereof, one longitudinal wall of said body portion being thickened at its upper portion to increase the strength thereof, and the flaring of the lower portions of the sockets facilitating the discharge of materials therefrom.

3. A grate-bar comprising a body portion having elongated sockets formed therein, the said sockets having flaring-outlets at their lower ends, removable fuel-engaging caps mounted upon the bar and provided with shanks extending into the said sockets, the body portion being formed with V-shaped lugs arranged in each of said sockets projecting from one of the walls thereof to hold the lower ends of the shanks in position, and the inclined surfaces of the V-shaped lugs preventing the collection of ashes or dust in the sockets.

4. A grate-bar, comprising a socketed body portion having an abutment edge rising from one of its side walls and removable caps each having a shank formed to fit into a socket of the body portion of the bar and laterally-extending webs, some of which are formed with recesses capable of fitting upon said abutment edge of the cap portion of the bar.

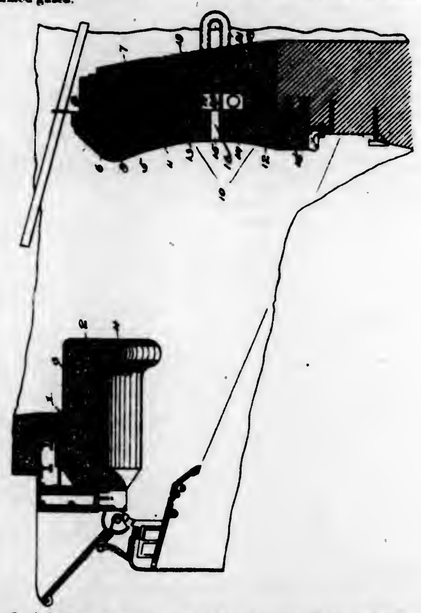
5. A grate-bar, comprising a socketed body portion having an abutment edge rising from one of its side walls and removable caps each comprising a shank formed to fit into a socket of the body portion of the bar and laterally-extending webs, the webs upon one side of the shank being shorter than those upon the other side, the said short webs being formed with recesses capable of fitting upon said abutment edge of the body portion of the bar.

6. A grate-bar, comprising a body portion and removable caps having ends adapted to be driven into fuel and shanks engaging the said body portion, the body portion having walls of unequal heights, the higher wall engaging the shanks at higher points, than the lower wall, so as to be approximately opposite the ends of the caps with respect to the shanks and forming abutments for driving the caps into the fuel when the bar is rocked.

812,072. **FURNACE-COMBUSTION-CHAMBER STRUCTURE.** WILLIAM MCCLAVE, Scranton, Pa., assignor to McClave-Brooks Company, Scranton, Pa. Filed Aug. 24, 1905. Serial No. 275,089.

Claim.—1. A furnace-combustion-chamber structure, comprising a bridge-wall having a parti-cylindrical portion, the curve of the cylindrical portion being struck on an arc from a point approximately central with respect to the fuel on the grate of said furnace.

2. In a furnace-combustion-chamber structure, the combination of a bridge-wall having its front face curved for concentrating the heat centrally of the furnace-grate and a front arch overhanging the said grate and formed with a downwardly-extending retaining edge adapted to direct gases toward the center of the said grate for coacting with the said bridge-wall for preventing the escape of unconsumed gases.



3. A furnace structure comprising a bridge-wall having a partially-cylindrical front surface, the axis of said cylindrical portion being central with respect to the furnace-grate.

4. A bridge-wall structure comprising a wall formed with a discharge-opening leading into the combustion-chamber of the furnace, an air-passage being formed within said wall, and a tube extending from said passage through the rear portion of the wall and to a point supplying air to said discharge-opening.

5. In a furnace-combustion-chamber structure, the combination with a bridge-wall having a plurality of passages arranged therein, one of said passages adapted to be supplied with air, of a pipe leading from one of said passages to a point for being supplied with heat from the combustion-chamber, and extending to the other of said passages, means of communication being provided between said other passage and the combustion-chamber.

6. In a furnace-combustion-chamber structure, the combination with a bridge-wall formed with openings leading into the combustion-chamber, a passage being formed in the bridge-wall communicating with said discharge-openings, a plurality of pipes communicating with said passage and extending beyond the bridge-wall to a point for being heated, and means within the bridge-wall for supplying air to said pipes.

7. In a furnace-combustion-chamber structure, the combination with a bridge-wall, provided with a plurality of air-passages, and means of communication between one of said passages and said combustion-chamber, of a U-shaped tube connecting said passages and extending to a point for being subjected to the action of heat from the combustion-chamber.

8. A bridge-wall structure for furnaces, comprising blocks arranged in proper relation and having their front edges curved to form a partially-cylindrical surface upon the front of the wall, the axis of said partially-cylindrical surface lying near the center of the combustion-chamber of the furnace and an overhanging ridge made up of anchored blocks arranged near the upper edge of said bridge-wall.

9. In a furnace-combustion-chamber structure, the combination with a hollow bridge-wall divided into passages, and pipes connecting said passages and extending beyond the rear face of the bridge-wall, means of communication between one of said passages and the combustion-chamber being provided, and means for supplying air to the other of said passages being also provided.

10. In a furnace combustion-chamber, the combination with a hollow bridge-wall divided into passages, means being provided for supplying air to one of said passages, and the other of said passages being provided with a discharge means communicating with the combustion-chamber, of a tube connecting said passages and extending beyond the face of the bridge-wall, that portion of said tube extending beyond the wall being arranged in an inclined plane.

11. A bridge-wall structure made up of fire-resisting bricks and blocks, said bricks and blocks being arranged to form air-ducts properly separated from each other, spacing-blocks arranged in the face of the bridge-wall adjacent to the fire-box of the furnace, the said blocks being slightly separated to form outlet-passages for one of the ducts in the bridge-wall, and pipes connecting the ducts and extending to the rear of the bridge-wall for subjecting the air which passes through the same to the action of the products of combustion.

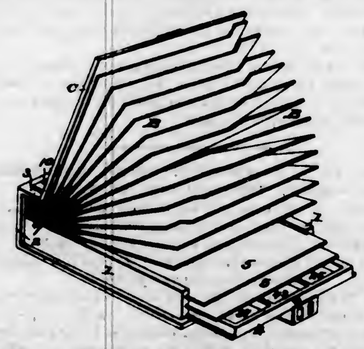
12. A bridge-wall structure for furnaces having upper and lower interchangeable blocks, spacing-blocks mounted between the interchangeable blocks and separated to form passages between them, an air-duct being formed in the bridge-wall to the rear of the spacing-blocks, air-conducting pipes extending from the said duct outwardly through the rear face of the bridge-wall and thence backwardly into the bridge-wall structure, the said bridge-wall being provided with a second lower duct communicating with the said pipes.

13. An air-feeding bridge-wall for furnaces, comprising a series of interchangeable facing-blocks, overhanging heat-directing blocks mounted above the said facing-blocks, transverse air-feeding ducts being formed in the bridge-wall to the rear of the said facing-blocks and having outlet-passages extending between the facing-blocks, looped pipes connecting the said ducts and arranged diagonally with respect to the ducts, the looped portions of the pipes extending to the rear of the bridge-wall for receiving the effect of the column of heated products which sweep downwardly over the bridge-wall.

14. A bridge-wall structure for furnaces comprising upper and lower interchangeable blocks, spacing-blocks interposed between the interchangeable blocks, and means for directing heated air to the combustion-chamber between the interchangeable blocks.

15. A bridge-wall structure for furnaces, the combination of upper and lower interchangeable blocks, partially inclosing an air passage-way, blocks interposed between said interchangeable blocks and spaced apart for affording a passage between said passage-way and the combustion-chamber, and means for supplying heated air to said passage-way.

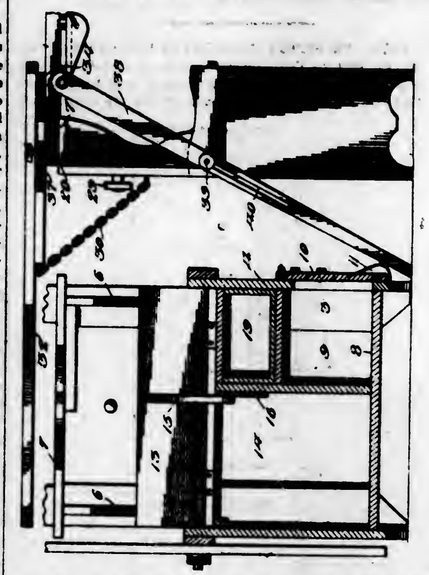
812,073. **POSTAGE-STAMP-BOOK CABINET.** JOSEPH P. MCDONALD, Philadelphia, Pa. Filed June 20, 1905. Serial No. 266,195.



Claim.—1. The improved postage-stamp cabinet, comprising a box-like base portion having a slidable drawer and plates arranged over the same and all spaced apart vertically, and a foldable portion comprising a series of stiff leaves and fixed back strips to which the same are hinged, the said strips being gradually increased in width from the top downward, the leaves being correspondingly increased in length from the bottom upward, and a rigid cover hinged to the back of the base portion in rear of the upper foldable leaves, substantially as described.

2. The improved postage-stamp cabinet comprising the box-like base portion having slidable holders for stamps, a superimposed series of hinged foldable leaves, and a stiff cover, and the clasp 11 hinged to the base and adapted to engage the cover whereby it secures the latter upon the leaves and holds the slidable parts in place, as shown and described.

812,074. **CABINET.** HARRY F. MCDONNELL, Latrobe, Pa. Filed June 24, 1905. Serial No. 266,747.



Claim.—1. The combination with a cabinet, of a standard hinged thereto and having a depending arm provided with an opening, a turn-button adapted for entrance through said opening and to be turned into engagement with the standard, and a board attached to and adapted for movement with the latter.

2. The combination with a cabinet, of a supporting-standard hinged thereto to swing from a vertical to a horizontal position, a depending arm carried by the standard, a latching member adapted for engagement with said arm to lock the standard in vertical position, an ironing-board attached to and for movement with the standard, and a supporting-leg pivoted between its ends and operatively engaged with the standard for automatic movement thereby to supporting position.

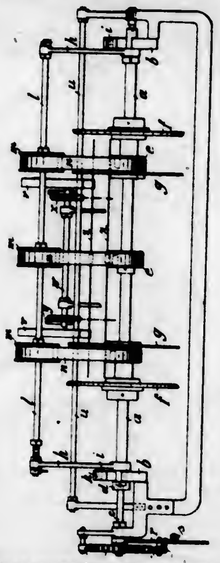
812,075. **SCREW-CONNECTING DIE AND STOCK.** WILLIAM J. MCKENNEY, Barnett, Ill. Filed Mar. 23, 1905. Serial No. 251,646.

Claim.—1. In a threading-tool, the combination of a stock, a rotary carrier held by the stock, said carrier being provided with sets of longitudinal slots, a holding-ring within the carrier, adjusting-screws connecting the ring to the carrier and adjustable in one set of slots to permit the ring to be adjusted toward and from the stock, radially-adjustable dies mounted in the carrier-ring, screws carried by the carrier-ring for radially adjusting said dies, said screws being adjustable in the other set of slots in the carrier, and means for rotating the carrier.

2. In a threading-tool, the combination of a stock provided with a chamber in one of the arms thereof, a cover for said chamber provided with a transverse slot, a rotary die-carrier held by the stock, said carrier being provided with ratchet-teeth, pivoted pawls mounted within the chamber and provided with portions to engage the ratchet-teeth to rotate the die-carrier in opposite directions, a spring arranged between and acting on said pawls to normally throw them into engagement with the ratchet-teeth, a transversely-sliding block ar-

ranged within the chamber and adapted to be adjusted in one direction or the other to throw the pawls alternately into and out of operation, and an adjusting member connected with the block and projecting exteriorly through and movable in the transverse slot in the cover, said adjusting member comprising a screw, whereby the block may be clamped in adjusted position.

812,076. **TRANSFER APPARATUS FOR WIRE HEDDLES.** ENGELBERT NEUHAUS, Crefeld, Germany, assignor of one-half to the Firm of A. Weyers & Cie., Crefeld, Prussia, Germany, doing business under the laws of the German Empire. Filed Nov. 9, 1903. Serial No. 180,394.



Claim.—1. In an automatic transfer apparatus for wire heddles and the like, the combination of a shaft with rollers or drums fastened to it on the periphery of which compartments of equal capacity are formed by a series of radially-arranged rods or equivalent means and bands or cords fastened by one end to these drums, which bands wind around the layers of heddles and hold them in place, substantially as described.

2. In an automatic transfer apparatus for wire heddles and the like, the combination of a shaft with drums, radially-arranged rods and ribbons fastened to these drums and placed upon upright arms at a certain distance from the main shaft, a counter-shaft with an equal number of drums to which the other end of the ribbons is fastened and so arranged that the ribbons on the drums of one of the shafts can unwind when the other shaft winds up, substantially as described.

3. In an automatic transfer apparatus for wire heddles and the like, the combination of the main shaft being detachably coupled to a stationary driving-shaft on which latter a ratchet-pawl mechanism is mounted, the feeding distance of which is equal to the division in compartments of the drums by the radially-arranged rods, substantially as described.

4. In automatic transfer apparatus for heddles or the like, the combination of a stationary horizontal shaft, a detachable shaft in line with and coupled to said stationary shaft, compartment wheels or drums on said detachable shaft, means on said stationary shaft for imparting intermittent movement to said shaft, a supporting-frame for both shafts, an upwardly-extending open-eyed journal secured to said frame and in which the detachable shaft is journaled, and a lateral extension out of line with said shaft and loosely mounted thereon and engaging with said journal for securing the shaft in position.

5. In an automatic transfer apparatus for wire heddles and the like, the combination of a second stationary shaft being placed at a distance above the stationary driving-shaft in line with and detachably connected to the counter-shaft of the apparatus, means for actuating the same by a bell-crank lever on the main shaft, a free wheel mounted on the second shaft, and a link chain running over the sprocket of the free wheel, held at one end by the bell-crank and at the other end by a stationary spring, and another common ratchet and stop on the second shaft for fixing the motions thus imparted, substantially as described.

6. The combination of an automatic transfer apparatus for wire heddles and the like, being connected with a wire-heddle machine or the like in a position for receiving, means for actuating the same and stationary open guides placed in an inclined position toward the transfer apparatus, guiding the objects coming from the machine into the compartments of apparatus as these are successively presented in rotation, substantially as described.

7. In an automatic transfer apparatus for wire heddles and the like, the combination of the main shaft, compartment-drums on the shaft, and two disks placed outside of the end drums on the main shaft, substantially as described.

8. In an automatic transfer apparatus for wire heddles and the like, the combination of drums with bands placed on its main and counter shafts, and a spiral spring compressible between one bearing and an adjustable collar on the counter-shaft for imparting friction and thus keeping the bands taut, substantially as described.

9. In automatic transfer apparatus for wire heddles or the like, the combination with the heddle-making machine and the like, of intermittently-rotatable compartment-wheels, curved elastic arrow-pointed fingers intermediate between said heddle-making machine and said compartment-wheels, and means for imparting a rocking semicircular movement to said fingers.

10. The combination of an automatic transfer apparatus for wire heddles and the like, being attached to or connected with a heddle-making machine in a position for feeding or discharging, means for actuating the same, and two or more stationary curved rods directed toward the main shaft of the apparatus between the radial rods, which arrest the heddles falling from the apparatus, so that the radial rods still control their movements, and open straight guides at the lower end of the curved rods by which the heddles pass one by one to the machine, substantially as described.

11. In an apparatus for the purpose specified, a shaft, rods extended radially from the shaft and forming walls of a plurality of compartments, and binding-bands attached to the shaft.

12. In an apparatus of the class described, the combination with a shaft, of a plurality of rods extended radially therefrom, a counter-shaft, and binding-bands engaged to wind around heddles on the first-named shaft, the said bands being given off from the counter-shaft.

13. In an apparatus for the purpose described, a shaft, a plurality of rods extended radially therefrom, means for placing heddles between the rods, and binding-bands for the heddles.

14. In an apparatus for the purpose described, a shaft, a plurality of rods extended from the shaft, guides for directing heddles between the rods, and devices for transferring heddle-wires to positions between the rods.

15. In an apparatus for the purpose specified, a shaft, rods extended radially therefrom, a rotary part, curved fingers carried by said rotary part and having curved resilient ends, and binding-bands secured at one end to the said shaft.

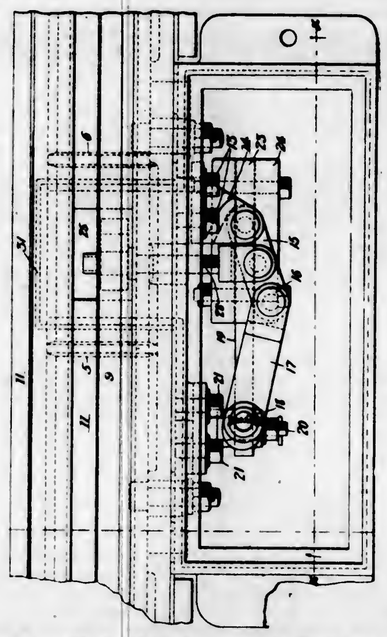
812,077. **SWITCH-LOCKING DEVICE.** HENRY H. NICHOLS, Philadelphia, Pa. Filed Nov. 11, 1905. Serial No. 286,881.

Claim.—1. In a railway-switch, the combination with a movable switch-tongue, of a stud rigidly connected thereto, a toggle-lever pivoted at one end, a connection between said stud and toggle-lever, and a weighted arm adapted to act upon the free end of said toggle-lever to hold the switch-tongue in its extreme positions.

2. In a railway-switch, the combination with a switch-tongue, and a depending stud connected thereto, a toggle-lever pivoted at one end, a weighted lever having connection between the toggle-lever and the depending stud on the switch-tongue whereby the weighted lever may throw the toggle-lever and the switch-tongue and hold them positively in their extreme positions.

3. A switch comprising a switch-tongue, a drop member thereon, actuating means engaging said member, a toggle-lever pivoted at one end and a bodily-movable element connected to the free end of said toggle-lever, said actuating means being secured to the toggle-lever, whereby the bodily-movable element is adapted to throw the switch-tongue through said means and to hold it in its extreme positions.

4. A switch comprising a switch-tongue, a depending stud thereon, a horizontally-movable device pivoted at one end, a connection between said depending stud and said device, and a vertically-movable weight connected to the free end of said device and adapted to throw the switch-tongue and to hold said switch-tongue in its extreme positions.



5. In a switch, the combination with a switch-tongue, of a depending stud secured thereto, a horizontally-movable toggle-lever pivoted at one end, a vertically-movable weight connected to the toggle-lever at its free end, and a connection between said toggle-lever and the switch-tongue whereby when said switch-tongue is moved the toggle-lever is positively held in its extreme positions.

6. In a switch, the combination with a switch-tongue, of a depending stud secured thereto, a horizontally-movable toggle-lever pivoted at one end, a connection between said toggle-lever and the switch-tongue, a weighted lever pivoted at one end and a stud connection between said weighted lever and said toggle-lever.

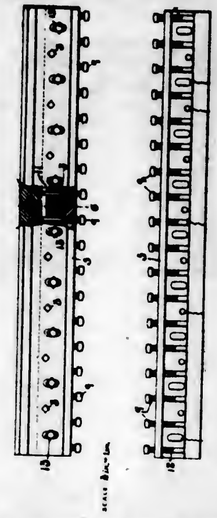
7. In a switch, the combination with a support, of a switch-tongue mounted to move thereon, a depending stud on said switch-tongue, a casing, a horizontally-movable toggle-lever pivoted within the casing, a connection between said toggle-lever and said switch-tongue, a vertically-movable weighted lever pivoted at one end, and a pin connection between said weighted lever and said toggle-lever whereby the toggle-lever is thrown to either extreme position when the switch-tongue is moved so as to carry it past the center.

8. In a switch, the combination with a support, of a switch-tongue adapted to move thereon, a depending arm upon the switch, a casing, ears secured to said casing, a toggle-lever pivoted at one end of said ears and provided with a long and short arm pivoted in the center, a connection from said short arm to the switch-tongue, a vertically-movable lever having a weight at one end, a post secured to the casing on which said weighted lever is pivoted, and a stud integral with said weighted lever, and movably secured to the long arm of the toggle-lever whereby when the toggle-lever is moved past the center by the tongue the weight of the lever is adapted to throw the toggle-lever and thus the switch-tongue, through their connection, to the extreme opposite positions.

9. In a switch, the combination with a switch-tongue base-plate, a switch-tongue mounted thereon, and operating parts for said switch, of a casing removably secured to the base-plate adapted to hold said switch parts, a trap adapted to drain said base-plate, and a slanting bottom to said casing and provided with an aperture to drain the casing.

812,078. **KNIFE-HOLDER FOR VENEER-LATHES.** MARTIN H. NORTON, Newport, Vt. Filed May 26, 1903. Serial No. 158,603.

Claim.—1. A knife-holder embodying a pair of clamping elements, a knife held between the elements, and means for transversely flexing a length of the knife edgewise or in the plane of the knife.



2. A knife-holder comprising a pair of clamping elements, a knife disposed between the elements, presser-pins engaging the rear edge of the knife, and means for exerting pressure on the pins to effect transverse flexing of a length of the knife.

3. A knife-holder embodying a pair of clamping elements, a knife disposed between the elements, clamping-screws for connecting the elements and locking the knife in position, presser-pins engaging the rear edge of the knife, and pressure-bolts coacting with the presser-pins to effect transverse flexing of the length of the knife.

4. A knife-holder embodying a pair of clamping elements, one of which is provided with spaced threaded orifices and open-sided recesses communicating therewith, a knife disposed between the elements, means for clamping the two elements together, presser-pins disposed within the recesses and engaging the rear edge of the knife, and pressure-bolts engaging the threaded orifices and coacting with the presser-pins to effect flexing of the knife.

812,079. **HEATING-STOVE.** ANSELM T. NYE, Marietta, Ohio. Filed Mar. 20, 1905. Serial No. 251,115.

Claim.—1. In a heating-stove, abutting sections each provided with a packing-groove in alinement with the groove in the other section and disposed diagonally to the line of jointure between the sections, and a packing disposed in said grooves.

2. In a heating-stove, abutting sections each having its edges provided with portions disposed in different horizontal planes and an intermediate diagonally-disposed packing-groove in alinement with the groove of the other section, and a packing disposed in said grooves diagonally to the line of jointure.

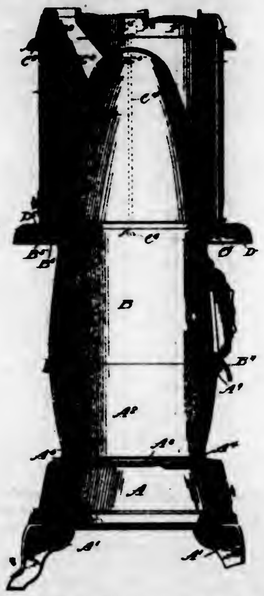
3. In a heating-stove, a body portion provided with a packing-groove at its upper face, a drum seated at its lower end in said groove, and a cap-plate for said drum provided with a depending flange in alinement with said groove to seat therein when the drum is removed.

4. In a heating-stove, a body portion provided with a packing-groove and flange and seat at its upper face, a drum seated at its lower end in said groove, a cover-plate for said drum, a dome provided with a flange and rib at its lower portion to rest upon the flange and seat upon said body, and a discharge-pipe from said dome extending through said cover-plate.

5. In a heating-stove, a body portion having at its top a supporting-flange and packing-groove, a dome disposed upon said flange, a drum surrounding said dome and extending at the outer face of said flange, a cap-plate located upon said drum and adapted to seat in said groove when the drum and dome are removed, and a conducting-pipe extending from the dome to said cap-plate.

6. In a heating-stove, a body portion having at its top a vertical flange and a laterally-disposed flange, a dome supported upon said

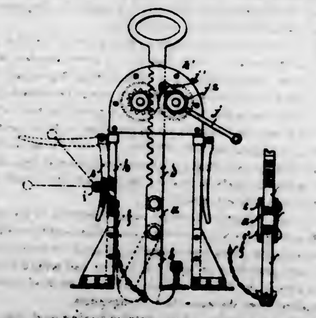
vertical flange, a drum surrounding said dome and the outer face of said vertical flange, a lateral extension from said drum disposed over the lateral flange of the body portion, and means for securing said extension and lateral flange in contact.



7. In a heating-stove, a body portion having at its top a vertical supporting-flange, and a laterally-disposed flange concentric thereto, a dome having a horizontal flange to rest upon the vertically-disposed flange and a depending flange extending within said vertically-disposed flange, a drum surrounding said dome and vertically-disposed flange, means for retaining said drum to the laterally-disposed flange, a cap-plate resting upon said drum, and a conducting-pipe extending from said plate to said dome.

8. In a heating-stove, a body portion provided at its top with a shoulder, a dome having a discharge-opening and a depending flange to rest upon said shoulder, a discharge-pipe from the upper portion of said dome provided with a flange to overlap the edges of said opening, a packing-recess beneath said overlapping flange, a vertically-disposed flange upon the stove-body at the outer side of said shoulder thereon, a cap-plate connected to said discharge-pipe, and a drum extending from said cap-plate to the outer face of the vertical flange upon the stove-body.

812,080. **RAIL-JACK AND THE LIKE.** FRANZ OBELIANDT, Fuerth, Germany. Filed Feb. 17, 1905. Serial No. 246,118.



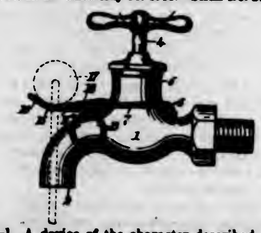
Claim.—A lifting-jack comprising an operating-gearing, a hook operatively connected therewith, the hook portion being mounted to swing, a hook-detaching lever, and a chain secured to said hook and slidably connected with said lever.

812,081. **COMBINATION-RACK.** JOHN S. OLIVER and CHARLES J. THOMAS, Baltimore, Md. Filed July 7, 1905. Serial No. 268,605.

Claim.—1. In a garment-rack, the combination of a casing, a stationary clamping element, a movable clamping element pivotally mounted in advance of its inner end within the casing and carrying upon its inner end an arcuate toothed rack and a locking projection, a spring bearing upon the inner end of the movable clamping member to force the same downward and the outer end upward, and a sliding spring-actuated dog adapted to engage the rack and adapted to be retracted by the key, the locking projection of the movable member being adapted to engage and lock the same from withdrawal when the dog is retracted.

2. In a garment-rack, the combination of a casing provided with supports for an umbrella or similar object, a stationary clamping element, a movable spring-retracted clamping element pivotally mounted upon the casing and provided with a rack and a key-locking element, a spring-actuated locking-dog to engage the rack, said dog adapted to be retracted by an inserted key, pivotally-mounted gripping-jaws for engaging the objects supported by the aforesaid supports, said jaws being provided with actuating-arms projecting into the casing, and a spreader pivotally attached to the inner end of the movable clamping element and movable between said arms to spread them apart and close the clamping-jaws.

812,082. **ATTACHMENT FOR FAUCETS.** GUSTAVE A. OLLEN, Providence, R. I. Filed May 16, 1905. Serial No. 260,693.

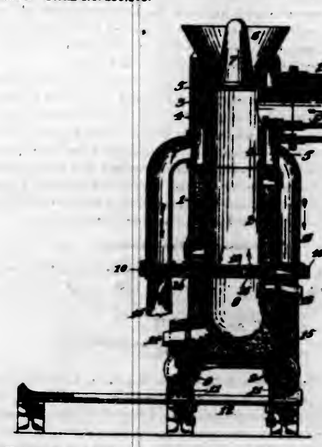


Claim.—1. A device of the character described, comprising a clasp for attachment to an upright portion of a faucet, a clamp for adjacent side portions of the discharge-spout of the faucet, and a hook for supporting the bail of a vessel.

2. A device of the character described, comprising a single piece of wire having the extremities thereof twisted together at the ends, thence curved outwardly and crossing each other to form an approximately circular clasp, the two members of the wire then being bent horizontally beyond the clasp, thence laterally and returned in the direction of the clasp and terminating in vertically-disposed sprung loops having a centrally-disposed transverse connecting-arch, the returned portions of said members being inwardly and upwardly inclined.

3. A device of the character described, comprising a single piece of wire having the extremities thereof twisted together at the ends, thence curved outwardly and crossing each other to form an approximately circular clasp, the two members of the wire then being bent horizontally beyond the clasp, thence laterally and returned in the direction of the clasp and terminating in vertically-disposed sprung loops having a centrally-disposed transverse connecting-arch, each of the connected portions of the device beyond the clasp being upturned to form a hook.

812,083. **SMELTING-FURNACE.** ALLEN R. PARTRIDGE, San Francisco, Cal., assignor, by mesne assignments, to The Vancedora Mine Equipment Company, a Corporation of California. Filed Oct. 26, 1904. Serial No. 230,670.



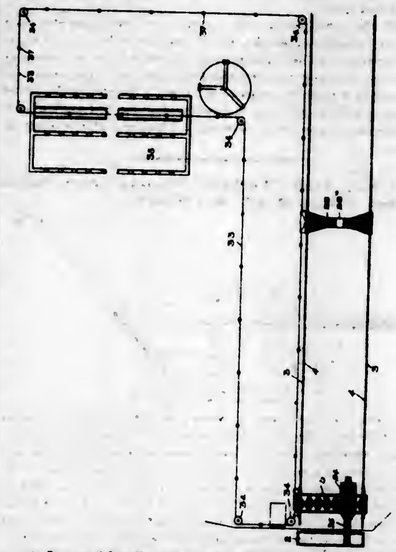
Claim.—In combination with a smelter, having a double wall near its upper end forming a hot-air space, an outlet-pipe communicating with the interior of the stack, an inlet-pipe concentric therewith and communicating with the hot-air space, an exhaust-fan in connection with the outlet-pipe, and a fan-blower in connection with the inlet-pipe.

812,084. **COAL-HANDLING PLANT.** WILLIAM J. PATTERSON and LEWIS J. ROSS, Pittsburg, Pa., assignors to Heyl & Patterson, Pittsburg, Pa., a Copartnership. Filed Jan. 9, 1904. Serial No. 188,385.

Claim.—1. In a coal handling and storage plant, the combination of a suitable track, an elevated traveling bridge on said track, a conveyer on said bridge, a carriage adapted to travel across said bridge, an outwardly-projecting frame on said carriage, a coal-lifting device carried by said frame and adapted to discharge the coal onto said conveyer, and a conveyer traveling parallel with said track and adapted to receive the coal from said first-mentioned conveyer.

2. In a coal handling and storage plant, the combination of a suitable track, a traveling bridge on said track, a coal-lifting device carried by said bridge, a series of buckets traveling parallel with said track and adapted to receive the coal from said coal-lifting device, a traveling frame on said track in the rear of said bridge, and an elevator on said frame adapted to receive the contents of said buckets.

3. In a coal handling and storage plant, the combination of a suitable track, an overhead traveling bridge on said track, a coal-lifting device carried by said bridge, a series of overhead traveling buckets parallel with said track and adapted to receive the coal from said coal-lifting device, a traveling frame on said track in the rear of said bridge, and an elevator on said frame adapted to receive the contents of said buckets.



4. In a coal handling and storage plant, the combination of a track, a double inclined traveling frame on said track, an inclined elevator on said frame, and a discharge-chute at the upper end of said frame into which said elevator discharges its contents.

5. In a coal handling and storage plant, the combination of a track, a series of overhead traveling buckets traveling parallel with said track, an elevated traveling frame on said track, an elevator on said frame adapted to receive the contents of said conveyer, and a discharge-chute at the upper end of said frame into which said elevator discharges its contents.

6. In a coal handling and storage plant, the combination of a track, a traveling frame on said track, an elevator on said frame, a chute at the lower end of said frame adapted to discharge into said elevator, and a discharge-chute at the upper end of said frame into which said elevator discharges its contents.

7. In a coal handling and storage plant, the combination of a track, a double inclined traveling frame on said track, an inclined elevator on said frame, and two or more discharge-chutes at the upper end of said frame into which said elevator discharges its contents.

8. In a coal handling and storage plant, the combination of a suitable track, a traveling bridge on said track, a coal-lifting device carried by said bridge, a conveyer traveling parallel with said track adapted to receive the coal from said coal-lifting device, a traveling frame on said track in the rear of said bridge, and an elevator on said frame adapted to receive the contents of said conveyer.

9. The combination with apparatus for unloading materials from cars, barges and the like, and means independent of said apparatus for placing said materials in storage, of means for adapting said unloading apparatus for use in reclaiming the stored materials from any desired point of the storage pile.

10. The combination with apparatus for unloading materials from cars, barges and the like, and means independent of said apparatus for conveying said materials to a distance from the unloading apparatus and depositing them in storage, of means for adapting said unloading apparatus for use in reclaiming the stored materials from any desired point of the storage pile.

11. The combination with movable apparatus for unloading materials from cars, barges and the like, and means independent of said apparatus for conveying said materials to storage, of means for transporting said unloading apparatus to any desired point of the storage pile to be used in reclaiming the stored material from storage.

12. In a coal handling and storage plant, the combination of a suitable track, an elevated traveling bridge on said track, and coal or like lifting device carried by said bridge, independent means for

placing in storage the coal lifted by said lifting device, and means for moving said traveling bridge along said track, whereby said lifting device may be employed to reclaim the coal from the storage pile at any desired point.

13. The combination with apparatus for unloading materials from cars, barges and the like, and means independent of said apparatus for placing said materials in storage, of means for adapting said unloading apparatus for use in reclaiming the stored materials from any desired point of the storage pile, and means for moving said unloading apparatus to any desired point of the storage pile to be used in reclaiming the stored material from storage.

812,085. **PLATE-JOINT.** ALEXANDER M. PEARCE, Pittsburg, Pa. Filed Aug. 19, 1905. Serial No. 274,844.

Claim.—1. In a plate-joint, the combination of the plates, the jaws thereof, a pin passing through the jaws, a plate carried by and shiftable with the pin, said plate having an eccentric edge extending across the joint between the jaws, means by which the pin and plate may be rotatably shifted, and clamping means to adjustably fix the pin.

its length, insulated electric wires severally connected to the secondary coil at intermediate points of its length and to the electric insulated wire leading from one pole of the primary coil, an electric

legs for said side section, folding leaves upon said side section, means for supporting said leaves in their open position, and means for retaining said side platform-section in its folded position between

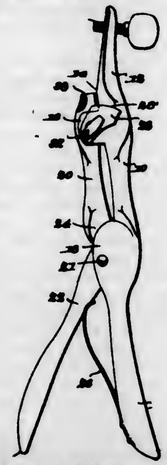
placing in storage the coal lifted by said lifting device, and means for moving said traveling bridge along said track, whereby said lifting device may be employed to reclaim the coal from the storage pile at any desired point.

13. The combination with apparatus for unloading materials from cars, barges and the like, and means independent of said apparatus for conveying said materials to a distance from the unloading apparatus, means for depositing said materials in storage, means for adapting said unloading apparatus for use in reclaiming the stored materials from storage, and means for adapting said original conveying means to convey the materials so lifted by said unloading apparatus.

812,085. PLOW ATTACHMENT. WILLIAM J. PATTETT, Centralia, Wash. Filed Jan. 23, 1905. Serial No. 242,216.

Claim.—A plow having its beam projecting laterally landward beyond the land-side plane of the share and standard, a jointer comprising a standard attached to and depending from the land-side face of the beam, an arm connected end to end to the lower end of the standard for axial movement, and a rotary disk cutter journaled on said arm and disposed on that side thereof which is opposed to the land-side plane of the plow, the lower edge of the disk cutter being disposed without the land-side plane of the plow to cut and turn a shallow, narrow furrow on the side next to the land side of the plow and in advance of, to the land side of, and out of line with, the large furrow made by the plow, substantially as described.

812,086. SAW-SET. ALONZO H. PRINCE, Somerville, Ala. Filed Aug. 22, 1904. Serial No. 221,769.



Claim.—1. A saw-set comprising a pair of members, a rotatably-shiftable pivot-pin piercing the members as a fulcrum connection therefor and projected at opposite sides of the members, each projected end having a non-circular portion, one terminal being provided with a finger-piece and the opposite terminal being threaded, gage-plates having non-circular openings receiving the respective non-circular portions of the pin and provided with corresponding eccentric edges extending across the joint between the pivotally-connected members, and a clamping-nut fitted to the threaded terminal of the pin.

2. A saw-set comprising a pair of cooperating jaw members, a rotatably-shiftable pin piercing one of the jaw members, a gage-plate carried by and shiftable with the pin, said plate having an eccentric edge extending across the joint between the jaws, means by which the pin and plate may be rotatably shifted, and clamping means to adjustably fix the pin.

812,087. MOISTENING DEVICE. PIER A. PETERSON, New York, N. Y., assignor to Frank P. Hunt, Nyack, N. Y. Filed May 23, 1905. Serial No. 261,769.

Claim.—1. A moistening device comprising a chambered body provided with a lower opening, a roller mounted to revolve at the opening in the body, a slotted guard-plate located above the roller within the body, a cover for the body, a handle adjustable in the cover, and a follower secured to the handle.

2. In a moistening device, a box-body having an opening in its lower portion extending through from front to rear, a moistening-roller journaled in the sides of the body at the said opening, a slotted guard-plate located above the roller within the body, a handle, means for adjusting the said handle relative to the body, and a follower secured to the handle and being normally located within the body.

3. A moistening device consisting of a box-body having a lower opening extending through from front to rear, a moistening-roller journaled in said body at said opening, an upwardly-arched slotted guard-plate secured within said body above said roller, the side edges of which plate extend out through the said front and rear openings, a cover for the body, a handle adjustably connected with the cover, and a follower secured to the inner end of the said handle.

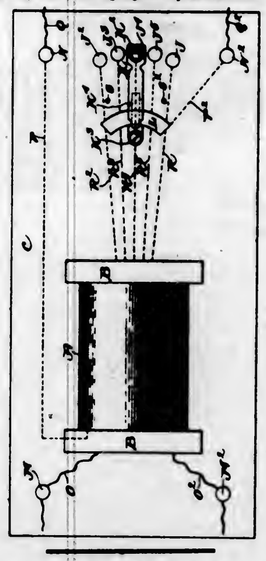
4. A moistening device consisting of a box-body having an opening at its lower portion extending through from front to rear, a moistening-roller journaled in said body at the said opening, a slotted guard-plate secured within the body, the longitudinal edges of which guard-plate extend out through the openings in the body, a cover hinged to the said body, which cover is provided with a central opening and an interiorly-threaded collar around the opening, a handle having an exteriorly-threaded portion which is fitted to the said collar, and a follower attached to the inner end of the handle.

812,088. CARTRIDGE-EXTRACTING IMPLEMENT. WALTER W. PITMON, Marco, Cal. Filed Dec. 30, 1902. Serial No. 137,141.

Claim.—In a device of the class described, a tubular sleeve wholly composed of a plurality of cooperating relatively movable segmental sections, an external series of rearwardly-pitched teeth or serrations provided on and extending peripherally of the sleeve, said teeth being extended beyond the plane of the face of the sleeve and the latter having its interior wall gradually and diminishingly tapered from front to rear, a correspondingly-tapered mandrel fitted within and free from positive engagement with the sleeve to permit relative sliding and rotary movement of the parts, said mandrel having its forward larger end rounded and being of greater length than the sleeve, whereby said rounded end may be projected in advance of the sleeve to facilitate entrance of the device into a shell, and a disk-like head fixed on the rear smaller end of the mandrel.

812,089. ELECTRIC TRANSFORMER AND CONNECTIONS. HERBERT F. PROVANDIE, Malvern, Mass. Filed Nov. 11, 1904. Serial No. 232,366.

Claim.—A primary coil or winding, a secondary coil or winding within the primary coil, a core of bunched longitudinal wires within the secondary coil, wooden heads supporting the opposite ends of the core, insulation of primary and secondary coils and of core and secondary coil, and surrounding primary coil, a closed shell or case containing primary and secondary coils, core and wooden heads and their said insulations, and iron particles packed within the shell about the insulation surrounding the primary coil, in combination with insulated electric wires, one leading from one pole and another from the opposite pole of the primary coil and respectively connected to the opposite poles of any suitable source of electric energy, a series of electric contacts, insulated electric wires, one connected to each of the electric contacts and the others connected to the secondary coil, but severally at separate intermediate points and at one end only of its length, insulated electric wires severally connected to the secondary coil at intermediate points of its length and to the electric insulated wire leading from one pole of the primary coil, an electric switch arranged to be placed in and out of contact with each of said electric contacts, and an insulated electric wire connected to said switch and to a binding-post separate from the binding-post connected to one pole of the primary coil, all as substantially as described and for use and operation and purposes specified.



812,090. BANANA-CRATE. HENRY ROSE, Shreveport, La. Filed Apr. 13, 1905. Serial No. 255,303.

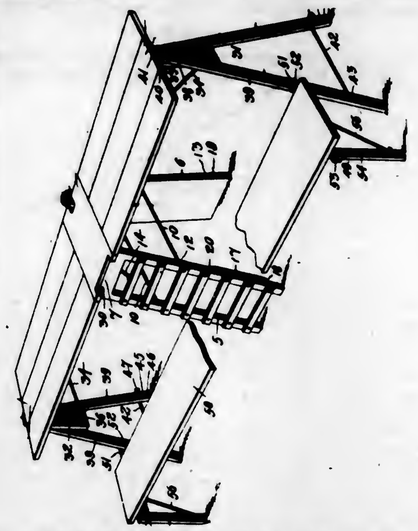
Claim.—The herein-described banana-crate consisting of the two separable longitudinal sections comprising end pieces 2 with longitudinal slats 4 secured thereto, tongues 5 on the end pieces of one section to extend across the end pieces at their juncture and keepers 8 on one section to accommodate the tongues, fasteners 10 passing through the keepers and tongues and keeper-plates 12 for holding the fasteners in place, a pasteboard lining arranged in said crate, and packing-rolls connected longitudinally to the slats and pasteboard lining, substantially as described.

812,091. COMBINED SCAFFOLD AND STEP-LADDER. JOHN H. ROSE, Shreveport, La. Filed May 5, 1905. Serial No. 259,940.

Claim.—1. A device of the character described, comprising a main platform-section, supporting-legs hingedly connected at the front and rear ends of the same, side platform-sections hingedly connected to the sides of said main platform-section and adapted to fold between said supporting-legs, and foldable legs upon said side platform-sections.

2. A device of the character described comprising a main platform-section having supporting-legs, one being in the form of a step-ladder, means for bracing said legs apart, a collapsible side platform-section adapted to be folded between said supporting-legs, and means for retaining said side platform-section between said legs.

3. A device of the character described comprising a main platform-section, hinged supporting-legs upon the same, one being in the form of a step-ladder, means for bracing said legs apart, a side platform-section hinged to said main section, foldable supporting-legs for said side section, folding leaves upon said side section, means for supporting said leaves in their open position, and means for retaining said side platform-section in its folded position between said supporting legs.

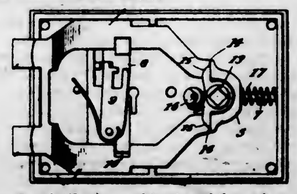


4. A device of the character described comprising a main platform-section, supporting-legs hinged thereto, one being in the form of a step-ladder, hook-rods for bracing said legs apart, a side platform-section consisting of a center board hinged at one of its ends to said main section, hinged leaves upon said center board, turn-buttons for supporting said leaves in their open position, a block hinged upon the outer end of said center board, a brace-rod for holding said block in its open position, folding legs pivotally mounted upon said block, and a brace-rod for connecting the latter-mentioned legs.

5. A device of the character described comprising a main platform-section having a recessed portion at one of its ends and a wheel or roller journaled at its other end, supporting-legs hinged upon the under side of said main section, the leg adjacent to said recess being in the form of a step-ladder, a hook-rod for bracing said legs apart, side platform-sections each consisting of a center board hinged at its inner end upon one side of said main section, leaves hinged upon the sides of said center boards, turn-buttons for supporting said leaves in their open position, a hinged block at the other end of each of the center boards, detachable brace-rods engaged with said block, legs pivoted upon said blocks, a hook-rod for bracing said legs apart, means for adjusting one or more of said legs, and means for retaining said side platform-sections in their folded positions between the first-mentioned supporting-legs.

6. The combination with the supporting-legs of a scaffold, of folding frames pivotally connected thereto and each consisting of a horizontal member, a pivoted vertical member or leg and a detachable brace-rod, and a table-top removably mounted upon the horizontal members of said frame.

812,092. DOOR-LATCH. EDWARD H. ROY, Nashville, Tenn. Filed Feb. 18, 1905. Serial No. 246,286.



Claim.—In a latch, the combination of the casing, a latch-bolt comprising similar members connected at their inner ends by means of a yoke, a knob-spindle hub fitted in the yoke and having its arms

arranged to engage with the extremities of said yoke, a guide-pin located upon one side of the knob-spindle hub and

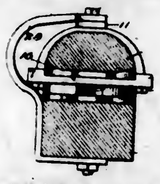
annular extension provided with notches formed upon its periphery

rigid member and a lower turning member projecting below the said

lel with the tank, characterized by having

arranged to engage with the extremities of said yoke, a guide-pin located upon one side of the knob-spindle hub and having engagement with said yoke, and a post upon the opposite side of said knob-spindle hub to form a stop therefor and beveled upon opposite sides to provide ample movement for said hub, substantially as specified.

812,093. DOUBLETREE AND WHIFFLETREE COUPLING. GEORGE B. RUSSELL, Carrollton, Ill. Filed Apr. 19, 1905. Serial No. 256,336.



Claim.—1. A device of the character described comprising a primary plate provided with a central squared recess and an aperture, parallel ribs formed upon said plate, each of said ribs provided with a concave upper surface and with a vertical side, said plate provided with an annular extension formed upon its base, an auxiliary plate provided with a hollow annular extension projecting from its upper face, said annular extension of the auxiliary plate provided with squared notches, a draft-bolt positioned upon and securing said plates together, a removable clip carried by said primary plate, said removable clip provided with a threaded aperture, a clevis provided with apertured ends positioned upon said clip and draft-bolt, a crown-bolt positioned within one of the apertures of said clevis and threaded into the aperture of said clip, and means carried by said draft-bolt for securing said clevis in a fixed position thereon.

2. In a device of the character described, the combination with a support, of a primary and an auxiliary plate, parallel ribs formed upon said primary plate, each of said ribs provided with a beveled upper surface, said primary plate provided with a recess, a bolt provided with a squared head positioned upon said plates, the squared head of said bolt positioned within the squared recess of said primary plate, a removable clip carried by said primary plate, and means connecting the upper portion of said clip and the lower portion of said bolt with said support.

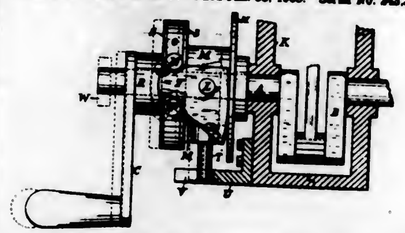
3. A device of the character described comprising a primary and an auxiliary plate, said primary plate, provided with an annular downward extension and a squared central recess, said auxiliary plate provided with an annular extension, said extension provided with notches formed upon its periphery means for securing said plates together, a clip carried by said primary plate, and means for securing said clip in a fixed position upon said plate.

4. A device of the character described comprising a primary and an auxiliary plate, said primary plate provided with ribs, each of said ribs having a beveled upper face and a vertical side, means for securing said plates together, a clip carried by said plates, means for securing said clip, primary and auxiliary plates in an assembled position.

5. In a device of the character described the combination with a support, of an auxiliary plate carried by said support, said auxiliary plate provided with a central recess and an aperture, squared notches formed upon said auxiliary plate, a primary plate provided with an aperture and an annular extension positioned upon said auxiliary plate, and having the annular extension projecting into the central recess, said primary plate provided with apertured, lateral extensions, ribs formed contiguous to said lateral extensions upon said plate, each of said ribs provided with beveled and vertical faces, said primary plate provided with a squared central recess and an aperture, the aperture of said primary plate registering with the aperture of said auxiliary plate, a draft-bolt provided with a squared head positioned within the central aperture of said primary plate and the registering aperture of said auxiliary plate, the squared head of said draft-bolt positioned within the squared recess of said primary plate, a removable clip carried by said primary plate, the ends of said clip positioned within the apertured portion of said lateral extensions, nuts positioned upon the ends of said clip, and means carried by said support and connecting the clip and draft-bolt with said support.

6. A coupling device comprising a primary plate provided with parallel ribs, each rib provided with vertical and beveled faces, said primary plate provided with apertured lateral extensions projecting therefrom, contiguous to said ribs, an auxiliary plate provided with an annular extension formed integral upon its upper surface, said annular extension provided with notches formed upon its periphery, said primary plate provided with an extension projecting downwardly therefrom and adapted to be positioned within the annular extension of said auxiliary plate, and means securing said plates together.

812,094. STARTING-CRANK FOR ENGINES. GEORGE B. SELDEN, Jr., Rochester, N. Y. Filed Jan. 30, 1905. Serial No. 243,260.



Claim.—1. The combination of a crank-shaft, a starting-clutch member revolving therewith, a starting-crank provided with a clutch member corresponding to that on the shaft, a non-rotating support, a movable lever on the support for disengaging said clutch members when said crank-shaft revolves backward, and means arranged at right angles to the axis of revolution to actuate said cam on said backward movement, as and for the purposes set forth.

2. The combination of a crank-shaft, a starting-clutch member revolving therewith, a part having a plane surface at right angles to the crank-shaft, a starting-crank provided with a clutch member corresponding to that on the shaft, a second clutch mounted on the starting-crank, and means operating between said second clutch and the plane surface to disconnect the starting-clutch members from each other, as and for the purposes set forth.

3. The combination of a crank-shaft, a starting-clutch member revolving therewith, a disk, a starting-crank provided with a clutch member corresponding to that on the shaft, and provided with a second clutch, and means operating between said second clutch and said disk to disconnect the starting-clutch members from each other, as and for the purposes set forth.

4. The combination of a crank-shaft, a starting-crank, a starting-clutch member revolving with said crank-shaft, a movable part having a plane surface at right angles to the crank-shaft, an oppositely-acting clutch member carried by the starting-crank, and means located between said clutch members and the plane surface for disconnecting said clutch members on the reverse rotation of the crank-shaft, as and for the purposes set forth.

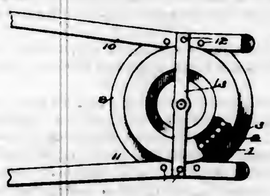
5. The combination of a crank-shaft, a starting-crank, a starting-clutch member revolving with said crank-shaft, a part having a plane surface at right angles to the crank-shaft, an oppositely-acting clutch member carried by the starting-crank, a non-rotating support, and means operating between the clutch members and the plane surface to disconnect the clutch members on the reverse rotation of the crank-shaft, as and for the purposes set forth.

6. The combination of a crank-shaft, a starting-crank, a starting-clutch member revolving with said crank-shaft, a part having a plane surface at right angles to the crank-shaft, an oppositely-acting clutch member carried by the said starting-crank, a non-rotating support, a lever pivoted to said support and bearing at one end against said plane surface and connected at the other end with the clutch member on the starting-crank, as and for the purposes set forth.

7. The combination of a crank-shaft, a starting-crank, a starting-clutch member revolving with said crank-shaft, a part having a plane surface at right angles to said crank-shaft, a clutch on the starting-crank, said clutch comprising an inner member having a part adapted to engage with the starting-clutch member, and an outer member adapted to engage with the inner member on the reverse rotation of the crank-shaft, a non-rotating support, and means attached to the support and operated by the outer member of said clutch for disconnecting the members of the starting-clutch, as and for the purposes set forth.

812,095. FIFTH-WHEEL. MATTHEW H. SHERWOOD, Scranton, Pa., assignor of one-half to Burnham K. Nyce, Scranton, Pa. Filed Mar. 9, 1905. Serial No. 249,295.

Claim.—1. A fifth-wheel for vehicles, comprising an upper rigid member and a lower turning member projecting below the said upper member to engage a support having a movable engagement with the upper member and an attaching portion formed upon the upper member and projecting in a plane below the plane of bearing and capable of perforation at any point for securing it to the running-gear of a vehicle.



2. A fifth-wheel for vehicles, comprising a lower supporting member having a bearing formed therein, an upper supporting member resting upon said lower member and overhanging the same and an attaching-flange projecting from the upper member in a plane below that of the plane of bearing of the upper member to which portions of a running-gear may be secured the lower supporting member extending sufficiently below the upper supporting member to engage a support.

3. A fifth-wheel for vehicles, comprising a lower supporting member, an upper member resting thereon and having inner and outer walls overhanging and inclosing the lower member and a lateral projecting horizontal flange extending outwardly from the upper member entirely around the same for attachment to any kind of running-gear the said lower supporting member projecting sufficiently below the upper member for attachment to adjacent parts of the running-gear.

4. A fifth-wheel for vehicles, comprising a lower circular member and an upper circular member, the upper member having downwardly-extending walls overhanging the lower member and laterally-extending flanges projecting from each of the said walls affording attaching means for various kinds of running-gear.

5. A fifth-wheel for vehicles, comprising a lower supporting member having an annular runway formed therein, antifriction bearing means mounted in said runway and an upper member fitting upon said lower member and having a bearing for engaging and resting upon said antifriction means, laterally-extending flanges projecting from the upper member and capable of receiving the reaches or hounds of various kinds of running-gear, the said flange affording means to which the portions of the running-gear may be bolted or secured at any point.

812,096. RAILROAD TANK-CAR. GEORGE L. SOUTHARD, Southard, Okla., assignor to Union Tank Line Company, Bayonne, N. J., a Corporation of New Jersey. Filed Mar. 27, 1905. Serial No. 252,356.

Claim.—1. A railroad tank-car in which buffing stresses are transmitted jointly by the tank and a stress-transmitting member parallel thereto, characterized by having in the tank connections with respect to such stresses a looseness which is taken up when a certain degree of buffing stress is attained, substantially as described.

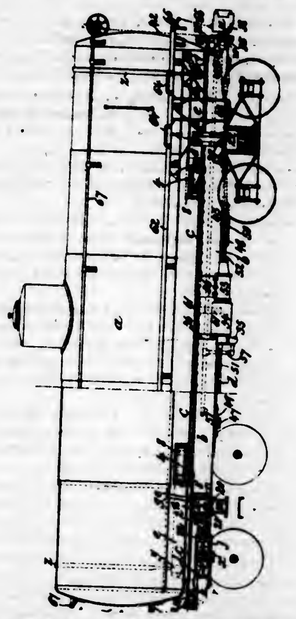
2. A railroad tank-car in which buffing stresses are transmitted jointly by the tank and a stress-transmitting member parallel thereto, characterized by having in the tank connections with respect to such stresses a looseness which is taken up by a small movement against large resistance, substantially as described.

3. A railroad tank-car in which buffing stresses are transmitted jointly by the tank and a stress-transmitting member parallel thereto, characterized by having in the tank connections with respect to such stresses a looseness which is taken up by the shortening of said parallel member under compression within its limit of elasticity, substantially as described.

4. A railroad tank-car in which buffing stresses are transmitted jointly by the tank and a stress-transmitting member parallel thereto, characterized by having constant and uniform tank connections with respect to pulling stresses, along with a limited looseness in the tank connections with respect to buffing stresses, substantially as described.

5. A railroad tank-car in which buffing stresses are transmitted jointly by the tank and a stress-transmitting member parallel thereto, characterized by having adjustable pulling connections for the tank along with buffing connections therefor which are loose to a limited extent, substantially as described.

6. A railroad tank-car with stress-transmitting member parallel with the tank, characterized by having longitudinally-adjustable pulling connections for the tank, substantially as described.



7. A railroad tank-car in which buffing stresses are transmitted jointly by the tank and a stress-transmitting member parallel thereto, characterized by having a limited looseness with respect to buffing stresses in the connections of a tank which is held from independent longitudinal motion not required for taking up said looseness, substantially as described.

8. A railroad tank-car with stress-transmitting member parallel with the tank, characterized by having tank connections at the ends of the tank, which connections restrain independent longitudinal motion otherwise while allowing expansion of the tank or shortening of the said parallel member to take place, substantially as described.

9. A railroad tank-car with two parallel stress-transmitting members, one of which is constituted by the tank, said car having a limited looseness in the tank connections with respect to buffing stresses and also having said members interconnected to prevent independent longitudinal movement except as such movement may be required in taking up said looseness, substantially as described.

10. A railroad tank-car composed of a tank, an underframe, and wheeled trucks, and characterized by tank connections which are loose to a limited extent with respect to buffing stresses, substantially as described.

11. A railroad tank-car composed of a tank, an underframe, and wheeled trucks, and characterized by tank connections which are loose to a limited extent with respect to buffing stresses, but tight with respect to stresses tending to move the tank bodily on the underframe, substantially as described.

12. A railroad tank-car having the tank removable from the body-bolsters and the buffing and pulling appliances and provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

13. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

14. A railroad tank-car composed of a removable tank, an underframe, and wheeled trucks, and provided with tank-attaching means which not only retain the tank in place on the body-bolsters, but also

support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

15. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

16. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

17. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

18. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

19. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

20. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

21. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

22. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

23. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

24. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

25. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

26. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

27. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

28. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

29. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

30. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

31. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

32. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

33. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

34. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

35. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

36. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

37. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

38. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

39. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

40. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

41. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

42. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

43. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

44. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

45. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

46. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

47. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

48. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

49. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

50. A railroad tank-car having a removable tank and also a parallel stress-transmitting member, the tank provided with attaching means which not only retain the tank in place on the body-bolsters, but also support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

support the buffing and pulling appliances and transmit buffing and pulling stresses between them and the tank, substantially as described.

15. A railroad tank-car having a saddle-plate under each end of a tank removably attached thereto, and also having buffing and pulling appliances permanently attached to said saddle-plate between the body-bolster and the end of the car, substantially as described.

16. A railroad tank-car having an underframe composed of cross-connected sills and saddle-plates, the former extending through the body-bolsters and receiving the buffing and pulling appliances between them, and the saddle-plates overlying said appliances and being permanently attached to said sills in proximity thereto so as to aid in upholding said appliances against stresses tending to depress the same, substantially as described.

17. A railroad tank-car having an underframe composed of cross-connected sills and saddle-plates permanently attached thereto, said sills extending through the body-bolsters, and the saddle-plates lying mainly between the bolster centers and the ends of the car, substantially as described.

18. A railroad tank-car having an underframe composed of cross-connected sills and saddle-plates permanently attached thereto, said sills extending through the body-bolsters, and the saddle-plates lying mainly between the bolster centers and the ends of the car and being attached to said sills between the bolsters and the ends of the car, substantially as described.

19. A railroad tank-car having saddle-plates and also longitudinal sills composed of flanged beams with flanges horizontal between said saddle-plates, these latter having seats on said sills conforming with their curvature, substantially as described.

20. A railroad tank-car having saddle-plates and also longitudinal sills composed of flanged beams with flanges horizontal between said saddle-plates and swaged under the latter to furnish seats conforming with the saddle-plates curvature, substantially as described.

21. A railroad tank-car having stress-transmitting longitudinal sills and also having means whereby buffing stresses are transmitted through the tank after being first received by the end portions of said sills, which car is further characterized by reinforcement of said end portions of the sills as compared with their middle portions, substantially as described.

22. A railroad tank-car having stress-transmitting longitudinal sills, and also having means whereby buffing stresses are transmitted through the tank after being first received by the end portions of said sills, which car is further characterized by saddle-plates secured to said end portions of the sills and connected with said tank for transmitting buffing stresses between it and the buffing and pulling appliances, substantially as described.

23. A railroad tank-car having saddle-plates which extend beyond the bolsters and are attached to the buffing and pulling appliances and which are also attached to the tank by tank-bands beyond the bolsters so that the ends of the tank constitute supporting cantalivers for upholding the buffing and pulling appliances, substantially as described.

24. A railroad tank-car having saddle-plates which extend beyond the bolsters and are attached to the buffing and pulling appliances and which are also removably attached to the tank beyond the bolsters so that the ends of the tank constitute supporting cantalivers for upholding the buffing and pulling appliances, substantially as described.

25. A railroad tank-car having saddle-plates located under the ends of the tank and removably connected therewith, and also having a separate set of bed-plank at each end of the tank between the latter and the corresponding saddle-plate, substantially as described.

26. A railroad tank-car having saddle-plates under the ends of the tank, and also having means for removably attaching each saddle-plate to the tank on both sides of the corresponding body-bolster, substantially as described.

27. A railroad tank-car having saddle-plates under the ends of the tank, and also having means for transmitting buffing stresses between the saddle-plates and tank and for removably attaching each saddle-plate to the tank on both sides of the corresponding body-bolster, substantially as described.

28. A railroad tank-car composed of a tank, an underframe, and wheeled trucks, said underframe being composed of longitudinal sills which receive the draft-rigging between them and with saddle-plates which overlie said draft-rigging, and said tank resting in said saddle-plates and connected therewith by tank-bands and by means to restrain independent longitudinal and rotary movement on the part of said tank, substantially as described.

29. A railroad tank-car having two sets of angle-pieces, bolted together, one set on the tank and the other set on parts by which the tank is supported, substantially as described.

30. A railroad tank-car having the tank connected with tank-supporting parts by bolts which extend lengthwise of the car, substantially as described.

31. A railroad tank-car having the tank connected with an underframe by bolts which extend lengthwise of the car, substantially as described.

32. A railroad tank-car having the tank connected with saddle-plates by bolts which extend lengthwise of the car, substantially as described.

33. A railroad tank-car having a tank with projecting devices on the bottom thereof on opposite sides of the longitudinal middle portion of said bottom, leaving the said middle portion clear, and also having means whereby buffing stresses can be communicated to the tank through said devices, substantially as described.

34. A railroad tank-car in which buffing stresses are transmitted through the tank by contact of projecting devices on the tank with tank-supporting parts with which said devices are out of contact in the absence of buffing stress, substantially as described.

35. A railroad tank-car composed of a tank, an underframe of longitudinal sills and saddle-plates, and wheeled trucks, and further characterized by projecting devices on the tank normally out of contact with opposing parts of the underframe and also by means for holding the tank in place on said underframe while allowing such motion as results from expansion of the tank or shortening of the underframe, substantially as described.

36. A railroad tank-car composed of a tank, an underframe of longiudinal sills and saddle-plates, and wheeled trucks, and further characterized by projecting devices on the tank normally out of contact with opposing parts of the underframe, yet near enough to come together upon shortening of the underframe under buffing stress, substantially as described.

37. In combination with an underframe of longitudinal sills and saddle-plates, a tank provided with projecting devices secured to the tank laterally beyond the sills and longitudinally behind the saddle-plates, substantially as described.

38. In combination with an underframe, a removable tank provided with projecting devices having sloped faces for guiding the tank into position on the underframe, substantially as described.

39. In combination with an underframe, a removable tank provided with projecting devices having sloped faces for guiding the tank into position on the underframe, and vertical faces for communication of buffing stress when the tank is in position, substantially as described.

40. A railroad tank-car composed of an underframe, a tank, and wheeled trucks, and characterized by possessing each of the following features, namely, longitudinal sills extending through the body-bolsters and receiving the draft-rigging between them, saddle-plates lying mainly between the bolster centers and the ends of the car and being secured to said sills, tank-bands secured to said saddle-plates near the ends of the car, projecting devices secured to the tank laterally beyond said sills and longitudinally behind said saddle-plates, companion devices on said saddle-plates, and bolts between the two sets of devices, substantially as described.

41. A railroad tank-car having saddle-plates which lie mainly between the bolster centers and the ends of the car and which are provided near the car ends with combined tank-band brackets and push-pockets, substantially as described.

42. A combined tank-band bracket and push-pocket, substantially as described.

43. A push-pocket having a curved base, substantially as described.

44. A push-pocket composed of a curved base, a side wall, and a bottom, substantially as described.

45. A push-pocket composed of a curved base, a side wall, a back, and a bottom, substantially as described.

46. A combined bracket and push-pocket, composed of a base, a side wall, a ledge on one side of said wall to form the bottom of the push-pocket, and a ledge on the other side of said wall to form part of the bracket, substantially as described.

47. A railroad tank-car having sills which receive the draft-rigging between them and also having an open-bottomed nose-piece which is provided with lugs on opposite sides of the draw-bar opening in position to underlie the ends of a cross-support for said draw-bar, substantially as described.

48. A nose-piece having vertical attaching-flanges interconnected by a horizontal transverse web, and also having lugs on opposite sides of the draw-bar opening in position to underlie the ends of a cross-support for said cross-bar, substantially as described.

49. A nose-piece having a pulley-bracket secured thereto on one side of the draw-bar opening in said nose-piece, substantially as described.

50. A nose-piece having secured thereto a pulley-bracket in the form of a beat metal strip with its ends lapped and fastened to the nose-piece, substantially as described.

51. A pulley-bracket in the form of a beat metal strip with its ends brought together in a parallel position, provided with a lug for the end of the brake-chain, substantially as described.

52. A railroad tank-car having an underframe composed of longitudinal sills with outboard arms and center blocks, the center blocks which are located between said sills and are secured to the vertical webs thereof being open-topped and composed each of a horizontal plate and upright sides with a series of vertical transverse webs, substantially as described.

53. A center block for a bolster, composed of a horizontal plate, a circular disk on the under face of said plate, upright sides, and a series of transverse vertical webs, the spaces between said webs being open above, substantially as described.

54. A center block for a bolster composed of a horizontal plate, a circular disk on the under face of said plate, upright sides, and a number of transverse vertical webs decreasing in height toward the center, the spaces between said webs being open above, substantially as described.

55. A four-sided outboard bearing-arm, having a vertical web flanged on each of its four edges, and also having its bottom offset near its outer end to leave a side bearing, substantially as described.

56. A railroad tank-car having a tank with devices fastened thereto and arranged to make contact longitudinally of the tank with tank-supporting parts to which said tank is removably attached, and also having tight cover-plates inside the tank over the areas of fastening said devices, substantially as described.

57. A railroad tank-car in which buffing stresses are transmitted jointly by the tank and a stress-transmitting member parallel thereto, characterised by having on the cylindrical or body portion of the tank connections for such stresses in which connections is provided a looseness to be taken up when a certain degree of buffing stress is attained, substantially as described.

58. A railroad tank-car in which buffing stresses are transmitted jointly by the tank and a stress-transmitting member parallel thereto, characterised by having on the cylindrical or body portion of the tank connections for such stresses in which connections is provided a looseness to be taken up by a small movement against large resistance, substantially as described.

59. A railroad tank-car having tank seats or saddles underlying a removable tank not only at the regions of the body-bolsters, but also between said regions and the ends of the tank, and also having means for attaching the buffing and pulling appliances to said tank between said body-bolster regions and the ends of the tanks, substantially as described.

812,097. TRAM-CAR AND OTHER LIKE VEHICLE.

Herbert A. Stanley and John H. Abson, Preston, England. Filed Feb. 6, 1905. Serial No. 244,630.

Claim.—1. In tram-cars, or like vehicles, the combination with a body, of a dash secured to said body, said dash comprising longitudinally-grooved uprights, and segmental plates secured within the grooves of said uprights.

2. In tram-cars, or like vehicles, the combination with a body, of a dash secured to said body, said dash comprising sections, and clamping means for securing said sections in a fixed position.

3. In tram-cars, or like vehicles, the combination with a body, of a dash carried by said body, said dash comprising segmental sections, and clamping means for securing said sections in a fixed position.

4. In tram-cars, or like vehicles, the combination of a body provided with an outer wall, a top deck or roof formed upon said body and terminating upon one side near said outer wall, said outer wall and top deck forming a passage for permitting of drainage of said deck.

5. In tram-cars, or like vehicles, the combination with a body, said body provided with a ventilator, of a top deck or roof secured to said body above said ventilator, a side wall terminating above said ventilator, said side wall and deck provided with a passage therebetween providing a drainage for the top deck and opening outside of said ventilator.

6. In tram-cars, or like vehicles, the combination with a body structure, of a ventilator secured to said body, a superstructure formed upon said body, said superstructure provided with a passage extending from the floor thereof through said superstructure contiguous to the outside of said ventilator.

7. In a tram-car, or like vehicle, the combination with a body, of a superstructure formed upon said body, said superstructure provided with a passage opening upon one side of said body and contiguous to the floor of said superstructure, a slidable sash carried by said superstructure, said sash adapted to be positioned within said passage.

8. In a tram-car, or like vehicle, the combination with a body, of a roof or deck positioned upon said body, said roof or deck provided with a longitudinal rail, an outside wall positioned contiguous to said rail, said outside wall and rail spaced apart for forming a drain-passage.

9. In a tram-car, or like vehicle, the combination with a body, of a longitudinal rail secured to said body, an outside board secured contiguous to said rail, said board and rail spaced apart for forming a passage, a superstructure formed upon said body, a slidable sash of the roof-cover carried by said superstructure, said superstructure provided with a passage of greater width than and communicating with the passage formed between the board and rail, and said sash adapted to be positioned within the passage of said superstructure.

10. In a car, the combination with a stairs provided with a tread and a riser, said riser provided with an aperture, a hinged door secured to said stairs, adapted to be normally positioned parallel with said riser for closing said aperture, a catch carried by said stairs and normally engaging said door for securing it in a closed position, and an auxiliary catch secured to said stairs and being capable of engaging and retaining said door in an opened position parallel to said tread.

11. In tram-cars and other like vehicles, the combination with the perforated riser of the stairs that lead to the top deck, of a hinged flap and catch devices, so arranged that the flap can be folded against the riser to close the perforations, or be opened clear thereof, and be held in either position by one or other of the catch devices.

812,098. CELLULOSE COMPOUND AND PROCESS OF MAKING THE SAME.

Robert W. Strehlenert, Djursholm, Sweden, and Friedrich Reubold, Ludwigshafen-on-the-Rhine, Germany, assignors to Badische Anilin und Soda Fabrik, Ludwigshafen-on-the-Rhine, Germany, a Corporation. Filed Sept. 8, 1905. Serial No. 277,496.

Claim.—1. The process for the production of acetyl cellulose which consists in treating cellulose with an acetylating agent and with an acid which assists in promoting the reaction, in the presence of an indifferent solvent so that the acetyl cellulose remains undissolved.

2. The process for the production of acetyl cellulose which consists in treating cellulose with acetic anhydrid and with dilute sulfuric acid in the presence of an indifferent solvent so that the acetyl cellulose remains undissolved.

3. The process for the production of acetyl cellulose which consists in treating cellulose with acetic anhydrid and with dilute sulfuric acid in the presence of benzene so that the acetyl cellulose remains undissolved.

4. As a new article of manufacture a new form of acetyl cellulose which resembles cotton-wool in appearance, but has a hard feel and is brittle, is soluble in chloroform and acetone, and insoluble in water.

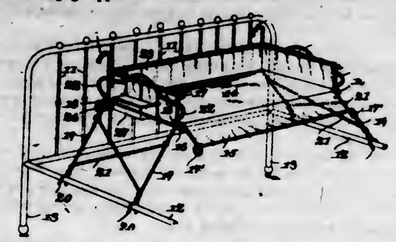
812,099. BABY-BED.

Arthur K. Taylor, Jacksonville, Fla. Filed Aug. 29, 1905. Serial No. 276,262.

Claim.—1. A crib arranged to be disposed transversely above a bed and having legs hinged to each end and proportioned to engage opposite side rails.

2. A crib arranged to be disposed transversely above a bed and

having legs associated in pairs and hinged to each end and proportioned to engage opposite side rails.



3. A crib arranged to be disposed transversely above a bed and having legs at each end provided with forked terminals proportioned to embrace the side rails.

4. A crib arranged to be disposed transversely above a bed and having legs hinged to the ends and each provided with a forked terminal proportioned to embrace the side rail.

5. A crib arranged to be disposed transversely above a bed and having legs associated in pairs and hinged to each end and each leg terminating in forked fingers proportioned to embrace the side rail.

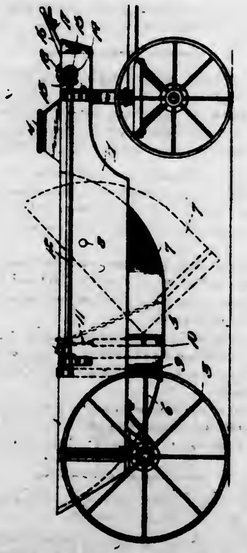
6. A crib having legs at each end means whereby the legs may be folded beneath the crib-body and means for varying the interval between the ends of the legs to correspond with the width of a bed and means carried by the legs to engage opposite side rails of the bed.

7. A crib having legs at each end arranged to fold beneath the crib-body and brace-pieces rigid with the legs and arranged to contact with the body-frame when the legs are unfolded.

8. A crib having legs hinged to each end and means for varying the operative interval between the legs to correspond with different widths of beds and means carried by the legs to engage opposite side rails of a bed.

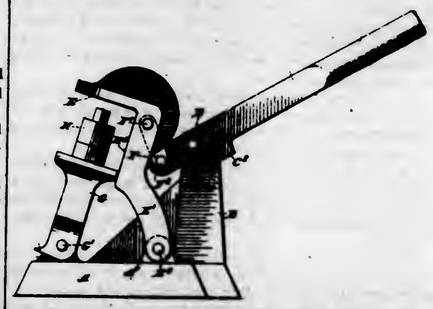
9. A crib having supporting-legs pivoted to its opposite ends and movable to inoperative position below the crib, side hooks projecting upward from the crib for engagement with a support, and a laterally-extended loop carried by the side of the crib and directed outward therefrom for engagement with a vertical portion of the support.

812,100. DUMPING-WAGON. GEORGE H. THOMAS, Philadelphia, Pa. Filed Mar. 11, 1905. Serial No. 249,618.



Claim.—In a device of the class described, a frame, a tray mounted therein and including a movable section, winding-shafts disposed upon opposite sides of the frame and having bevel-gears fixed thereon, flexible elements connected with said section and adapted to be wound upon the shafts, a counter-shaft extended between and having bevel-gears engaging those on the winding-shafts, a ratchet fixed on the counter-shaft, an operating-lever pivoted on the latter and having a pawl adapted for engagement with the ratchet to actuate the counter-shaft, and a latching member adapted for normally locking said shaft against rotation.

812,101. PRESS. HORACE THURSTON, Providence, R. I., assignor of one-half to Charles H. Schott, Brooklyn, N. Y. Filed July 13, 1905. Serial No. 269,226.

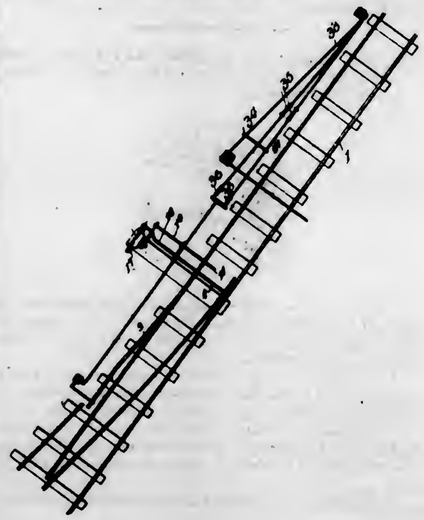


Claim.—1. A press comprising a base, swinging jaws each pivotally connected with said base, and a lever also pivotally mounted on said base and operatively connected with one of said jaws to swing it, one of the said jaws having a guide engaged by the other jaw, to cause one jaw to follow its mate as it is swung by the lever, so as to maintain both jaws in proper working relation to each other.

2. A press comprising a base, a swinging jaw pivoted thereto and provided with a guide, another jaw likewise pivoted to the base and arranged to lean and ride against the guide during the movement of the jaws, a lever fulcrumed on said base, and a link the ends of which are pivoted to said lever and to the first-named jaw respectively.

3. A press comprising a base, two swinging jaws pivoted thereto, one of said jaws being provided with a guide and the other with an engaging portion so arranged that gravity will cause one jaw to lean against the other and follow its movement, and means for swinging the jaw against which the other leans.

812,102. SWITCH AND SIGNAL. CHARLES TROUP, Watseka, Ill. Filed Sept. 30, 1905. Serial No. 280,788.



Claim.—1. In a railway-switch, the combination of the switch-point, a bar arranged transversely of the switch and having an end portion extending beneath the switch-point and the rail adjacent thereto and provided with a stop, a bell-crank lever having one arm connected to said bar and its outer arm connected to a signal, and means for operating said outer bar to project its stop into or out of the path of the switch-point and to simultaneously operate the signal.

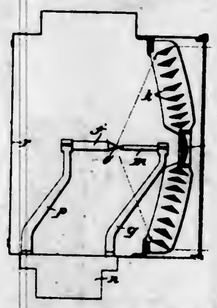
2. In a railway-switch, the combination of a switch-point, a pivoted bar having an end portion extended beneath the switch-point and the rail adjacent thereto and provided with a stop to engage with the switch-point, a bell-crank lever having one arm connected to said bar and the other arm connected with a signal, whereby the latter is simultaneously operated upon actuation of the bar to project its stop into or out of the path of the switch-point, a switch-stand, and connecting means between the operating-lever of the switch-stand and the aforementioned bar.

3. In a railway-switch, the combination of a switch-point, a lock therefor, a bar 15 operatively connected with the said lock, a switch-stand embodying an operating-lever 13, and connecting means between the operating-lever and the bar 15, whereby movement of the lever 13 to effect its release actuates the said lock and further movement of said operating-lever to throw the switch effects disconnection of said lever from the bar 15.

4. In combination, a movable switch-point, a lock therefor, a bar 15, connecting means between said bar and the lock, a switch-stand embodying an operating-lever 13, and a fork having swivel connection with the bar 15 and adapted to embrace the movable handle portion of the lever 13, whereby initial movement of the handle portion effects a release of the lock, and whereby a continued movement of the lever 13 disengages it from the swivel-fork

5. In combination with a switch, a signal and coöperative actuating means for the signal and switch, of a movable element 23, a pair of coöperating dogs 25, springs 30 conjunctively arranged with reference to said dogs, and corresponding pairs of arms 27 and 28, the parts being arranged to admit of independent operation of separate switch-operating mechanisms.

812,103. LIGHT-PROJECTOR. EMILE L. P. TURENNE, Paris, France, assignor to The Firm of Barbier, Benard & Turenne, Paris, France. Filed June 5, 1905. Serial No. 263,836.

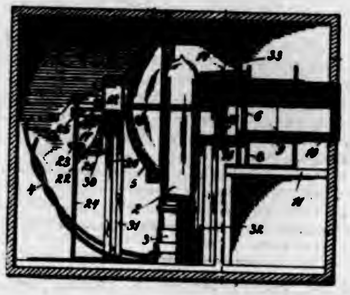


Claim.—In a projector, the combination with a source of light, of an optical device comprising a substantially concentric series of catadioptric glass rings arranged in a curve with an overlapping profile, substantially as described.

812,104. LOOP-SHIELD. ANTONE F. WARNER, Jackson, Mich. Filed Mar. 30, 1905. Serial No. 253,982.

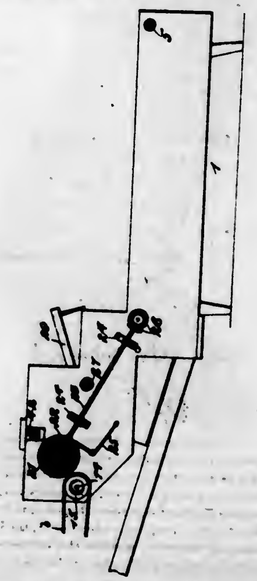
Claim.—A loop-shield made of a single piece of metal bent substantially U-shaped, lugs projecting from the longitudinal edges of said shield and bent over the outer faces thereof with their outer edges flush with the ends of the shield, lugs projecting from the edges of the plate at its longitudinal center and bent to form angled hooks extending over the bent portion of the shield, with spaces on either side of said lugs which project from the center of the shield, and the opposite parallel walls of the latter, as set forth.

812,105. ADVERTISING PROJECTING APPARATUS. FERDINAND WITZELEB and MAX OSBORNE, New York, N. Y. Filed Apr. 17, 1905. Serial No. 256,170.



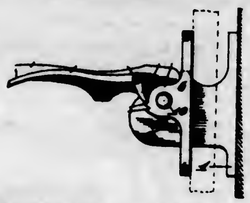
Claim.—An advertising apparatus consisting of a portable box, a reflector and projecting-lenses mounted therein, electric lights placed between said lenses and the reflector, a clockwork located to the rear of the reflector, a transparent dial located to the rear of the lenses in front of the lights, hands mounted on said dial, a connection from said hands to the clockwork, shafts, rolls mounted thereon, means for rotating one of the shafts from the clockwork and a plurality of indicating-belts mounted on said rolls and arranged to pass adjacent the dial, substantially as described.

812,106. SELF-FEEDING DERRICK-TABLE. VIRGIL WINN, Toler, Wash. Filed July 13, 1905. Serial No. 269,857.



Claim.—A machine of the class described comprising a table having a draper, a revolvable spiked roller spaced from the discharge end of the draper, a deflecting-board for the material which drops from the space between the draper and the spiked roller, a support under said deflecting-board, a carrier having one end resting on said support, said draper and spiked roller discharging on said carrier, and a rocking mechanism operating upon said spiked roller.

812,107. LATCH FOR REFRIGERATOR-DOORS. EDWARD J. WEBB, Memphis, Tenn. Filed Mar. 28, 1905. Serial No. 251,590.



Claim.—1. In a refrigerator-door latch, the combination with a keeper, a door-bracket, a latch pivoted to said bracket and adapted to engage said keeper, and a trigger pivoted to said latch and arranged to engage said bracket, substantially as set forth.

2. In a refrigerator-door latch, a keeper, a door-bracket, a latch pivoted to said door-bracket and adapted to engage said keeper, a trigger pivoted to said latch, and teeth forming a part of said door-bracket and adapted to receive the engagement of said trigger, substantially as set forth.

812,108. PLASTIC COMPOSITION. GEORGE C. WYATT, Rome, Ga. Filed May 6, 1905. Serial No. 259,222.

Claim.—A dry powder for plaster consisting of lime, sawdust, clay, sand, plaster-of-paris, and cement, in substantially the proportions stated.

812,109. FENCE-POST. GEORGE R. WYATT, Redwood City, Cal., assignor of one-fourth to Walter M. Barret and one-fourth to Edward F. Fitzpatrick, Redwood City, Cal. Filed Sept. 21, 1905. Serial No. 279,421.

Claim.—1. A metal fence-post, having a longitudinal channel therein said channel having parallel undercut side walls and an angular bottom wall, and also formed with a series of notches in corresponding corners of the post, a series of hook members spaced by the notches in said corners, and a keeper-key shaped to fit into the channel and insertible therein through one end thereof, the key when inserted bearing upon the fence-wire material that occupies the notches and is seated upon the bottom of the channel by the introduction of said key.

2. A fence-post having a quadrangular body, a longitudinal channel therein, and notched at intervals in corresponding corners, said notches intersecting the channel, said channel having its side walls undercut so as to widen it near the bottom thereof, said bottom having obtuse-angular form, a series of angular hook members at each corner that is adjacent to the channel, free ends of said hook members constituting the side walls of the channel, a fence-wire stretched in each pair of opposite notches across the bottom of the channel, and a keeper-key fitting in the channel and laterally below the hook members, the key being insertible only through one end of the channel, and adapted for bearing upon the fence-wires and kinking them into contact with the angular bottom of the channel.

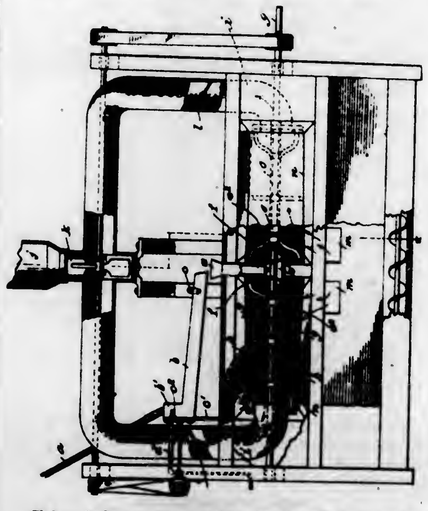
3. A corner-post to a fence, having a channel extended longitudinally in two sides that together form a right angle, each channel having parallel sides that are undercut, and the bottom of each channel rendered obtuse-angular in form, each of the three corners of the post nearest to the channels therein having spaced transverse notches therein which intersect respective channels, hook-like angular members on corners of the post spaced apart in series by the notches, and keeper-keys fitted loosely in respective channels so as to bear upon the fence-wire material that occupies the notches.

4. A keeper-key for a fence-post, rabbeted on side edges at opposite corners giving it T shape in cross-section, and thus adapted to slide endwise into an undercut channel in the side of said fence-post, whereby to secure fence-wire material embedded in the channel.

5. A fence-post having a transverse groove in the upper portion of its body having serrations in its bottom surface, and a brace-rod having a flat limb serrated on the transverse end wall thereof, said limb being adapted for entering the transverse groove and engaging the serrations on its end with those in the bottom of the groove.

6. A prop-brace for a corner fence-post, comprising a metal rod flattened near each end, and bent where flattened at an obtuse angle on the body of the brace-rod, thus producing a flat limb on one end that enters a transverse rectangular notch in a side of the corner-post near its upper end, and a notched or open slotted flange at the normally lower end of the brace-rod, said flange having straddling engagement with the lower portion of a line-fence post, whereby to hold the corner-post erect.

812,110. FLOUR BLEACHER AND PURIFIER. ROBERT I. AGNER, Salem, Va. Filed Mar. 25, 1905. Serial No. 252,040.



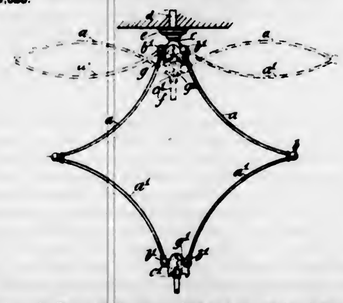
Claim.—1. In an apparatus of the class described, the combination of means for drying out and feeding the flour, and means for removing the lighter impurities, consisting of a casing closed except for the provision of air-inlets at its opposite sides about midway its length, a shaft running longitudinally through the casing, and carrying a pair of bolting-reels having their inner ends closed and located near each other, said reels each tapering toward its outer end, a chute adapted to receive the flour from the feeder and extending down between the inner ends of the reels, a horizontal open-ended tube communicating with said chute and having its ends extending into the adjacent inner ends of the reels, spring-actuated valves for the ends of this tube, reversely-curved screw-blades on the aforesaid shaft within said tube, exhaust-pipes extending out from the outer ends of the respective reels, and provided with valves and means for creating a suction through these exhaust-pipes for the purpose set forth.

2. In an apparatus of the class described, the combination of means for feeding the flour and means for subjecting the flour to the action of a current of air to remove the lighter impurities this latter means consisting of a casing closed except for the provision of air-inlets at opposite sides below the reels hereinafter mentioned, a shaft running longitudinally through the casing and carrying a pair of bolting-reels arranged end to end on the shaft, a chute adapted to receive the flour from the feeder and extending down between the inner ends of the reels, a horizontal open-ended tube communicating with said chute and having its ends extending into the adjacent inner ends of the reels, valves normally closing the ends of this tube, means on the shaft within the tube for oppositely feeding the flour past said valves simultaneously, exhaust-pipes extending out from the outer ends of the respective reels, and means for creating a draft up through the reels and the exhaust-pipes.

3. In an apparatus of the class described, the combination of a casing, a shaft extending longitudinally through the casing and carrying a pair of reels arranged end to end on the shaft, means for rotating the shaft and its reels, means for conducting flour down through the top of the casing and feeding it into both inner ends of the reels simultaneously, exhaust-pipes connecting the respective tail ends of the reels, means for creating a regulated suction through these pipes, said casing being closed all round except for the provision of inlet-openings below the reels, and a pair of brushes mounted upon opposite sides of the casing above the inlet-openings and engaging the opposite sides of the reels, these brushes serving not only to clean the meshes of the reels but also as partitions to direct the air-draft upward through the reels.

4. In an apparatus of the class described, the combination of a casing, a shaft extending longitudinally through the casing and carrying a pair of reels arranged end to end on the shaft, means for rotating the shaft and its reels, means for conducting flour down through the top of the casing and feeding it in through the center of both inner ends of the reels simultaneously, exhaust-pipes connecting to the respective tail ends of the reels, means for creating a regulated suction through these pipes, said casing being closed all round except for the provision of inlet-openings below the reels.

812,111. PENDENT GAS AND OTHER LAMP. FREDERICK A. ANDREWS, London, England, assignor to W. A. S. Benson and Company, Limited, London, England. Filed Oct. 13, 1904. Serial No. 229,085.



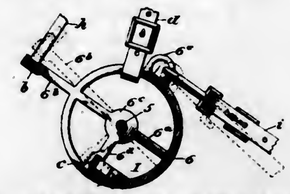
Claim.—1. In a pendent gas-lamp, the combination with the supply-pipe, of a union, a pair of sockets on said union, two hollow plugs each having one of its ends connected with one of said sockets, sockets on the other ends of said plugs, a pair of tubular arms connected with said second pair of sockets and having swiveled relation to the said union, intermeshing toothed sectors between the adjacent ends of said arms, hollow plugs connected to the other ends of said arms, a second pair of tubular arms pivotally connected to the first pair by means of said last-named plugs, a union for establishing connection with the burner, a third pair of hollow plugs pivotally connecting the second pair of arms in said union, and intermeshing toothed sectors between the adjacent ends of said second pair of arms, the arms all lying in planes substantially parallel with each other and at right angles to the planes of the plugs.

2. In a pendent lamp, the combination of a union, a pair of tubular arms pivotally jointed at their inner ends to said union, means for mechanically gearing the inner ends of said arms together, a second pair of tubular arms having their inner ends pivotally jointed to the outer ends of the first pair, a union, means for pivotally jointing the outer ends of said second pair of arms to said last-named union, means for mechanically gearing the inner ends of the second pair of arms together, and resilient rotation-opposing devices interposed at two of the joints.

3. In a pendent lamp, a pair of substantially parallel hollow plugs, means for connecting said plugs with a gas-supply pipe, a pair of partially-rotatable pipes connected to said plugs, means for gearing said pipes together so as to cause them to move in unison, a second pair of hollow plugs connected to said pipes and substantially parallel with the first pair of plugs, a second pair of pipes connected to said plugs and in a plane substantially parallel with the plane of the first pair of pipes, a third pair of hollow plugs substantially parallel with the first pair of plugs, means for connecting said third pair of plugs with a common burner-tube, means for gearing the second pair of pipes mechanically together, all of said pipes being capable of partial rotation about the axes of the respective plugs, and means for offering limited resistance to said rotation.

4. In a gas-pendant, the combination of two unions, a pair of tubular arms pivotally jointed to each other and to said unions on one side of the central line, a second pair of tubular arms pivotally jointed to each other and to said unions on the opposite side of said central line, intermeshing toothed sectors gearing said pairs of arms together near one of said unions, intermeshing toothed sectors gearing said pair of arms together near the other union, and springs coiled around the joints between the arms of each pair and connected to said arms for resisting their turning about the joint and so counteracting the weight of the lamp on the joints between the arms.

812,112. BRIDLE-BIT. ALONZO B. CAMPBELL, Coraopolis, Pa. Filed Mar. 8, 1905. Serial No. 248,985.



Claim.—A bridle-bit embodying two similar check-rings, each having a cross-bar and a central hub on each cross-bar, said hubs supporting a transverse bit-bar, a curb-bar extended down at a right angle from each cross-bar and merging into the body of the ring, said curb-bars each having a slot therein near the ring, an eye formed on each ring opposite the curb-bar, and a check-lever extended outside of each ring in alinement with the cross-bar therein and projected forwardly, said levers each having an opening at its free end for the engagement therewith of an end of an overdraw-rein.

812,113. EYEGLASS-MOUNTING. EDWARD M. CARD, Middlefield, Conn. Filed Oct. 6, 1905. Serial No. 281,690.

Claim.—1. In an eyeglass-mounting, lens-receiving heads, levers movably connected with the heads, nose-pieces carried respectively by the levers, and an operating member associated with and for moving the levers to adjust the nose-pieces relatively.

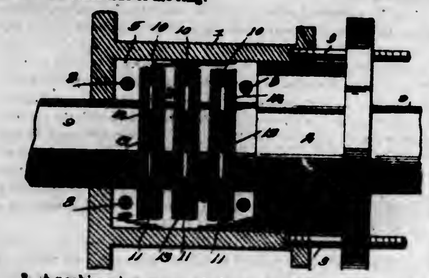
2. In an eyeglass-mounting, lens-receiving heads, a pair of levers pivoted between their ends respectively to the heads, nose-pieces carried by the levers, and an operating-screw connecting the levers and operable for moving the latter to adjust the nose-pieces relatively.

812,114. METALLIC PACKING. EDWARD M. COOK, Elyria, Ohio. Filed July 18, 1905. Serial No. 270,206.

Claim.—1. A packing-ring composed of a single set of segments having engaging ends, said ends being formed to provide radial cuts on one side and tangential cuts on the other side of the ring.

2. A packing-ring composed of segments, each having two integral portions, one set of portions of the several segments cooperating to form one half and the other set of portions the other half of the

body of the ring, said portions of the segments having their ends constructed to respectively form radial cuts on one side and tangential cuts on the other side of the ring.



3. A packing-ring composed of a single set of segments having engaging ends, said ends being formed to provide radial cuts on one side and tangential cuts on the other side of the ring, said radial and tangential cuts being disposed upon lines between each other so as to break joint around the surface of the ring.

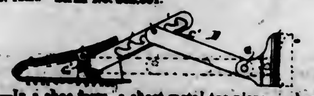
4. A packing-ring comprising segments, each composed of two parallel integral parts, one of said parts having its ends tangentially and the other radially beveled, irrespective tangentially and radially beveled parts of the several segments forming opposite sides of the body of the ring and tangential and radial cuts, the tangential cuts being disposed upon one side of the ring and the radial cuts upon the opposite side of the ring and on lines between said tangential cuts.

812,115. **DEVICE FOR FASTENING FOLDED PAPERS.** WILLIAM R. COON, Govanda, N. Y. Filed Nov. 26, 1904. Serial No. 234,802.

Claim.—1. A sheet having an uncut edge folded over upon the sheet and secured at a plurality of points to the said sheet, the body of the sheet being adapted to be folded and its opposing edge inserted under the folded edge between the secured points.

2. A sheet having one edge folded and secured at the sides and intermediate the sides, the body of the sheet being adapted to be folded and also have its opposite edge inserted beneath the folded edge of the sheet, the opposite edge being cut away in order to accommodate the secured portions of the folded edge.

812,116. **SHOE-FORM.** CHARLES B. CONNIN, Grand Rapids, Mich., assignor of one-half to Charles F. Aispuro, Grand Rapids, Mich. Filed Mar. 28, 1905. Serial No. 252,501.



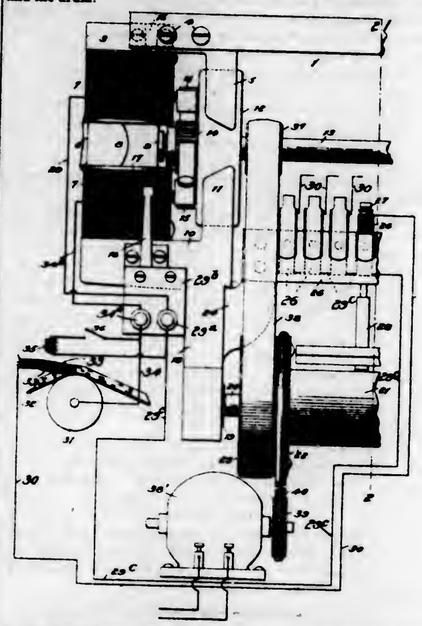
Claim.—In a shoe-form, a sheet-metal toe-piece, a sheet-metal sole-piece, a link pivotally attached to the toe-piece and the sole-piece, an adjustable toggle pivotally secured to the link and carrying a heel-piece.

812,117. **ELECTRICALLY ACTUATED AND CONTROLLED SELF-PLAYING MUSICAL INSTRUMENT.** GEORGE H. DAVIS, West Orange, N. J. Filed Mar. 28, 1904. Serial No. 200,494.

Claim.—1. An electrically-controlled playing attachment for musical instruments embodying a plurality of electromagnets, a dynamo forming a part of the attachment, circuit connections between the dynamo and said magnets, and a prime motor for driving the dynamo.

2. In an electrically-controlled musical instrument, a dynamo, electrically-controlled playing devices in circuit with the dynamo, and a prime motor to drive the dynamo.

3. In an electrically-controlled musical instrument, the combination with a drum and magnet-controlled playing devices, of a dynamo in circuit with said magnets and a motor to drive said dynamo and the drum.

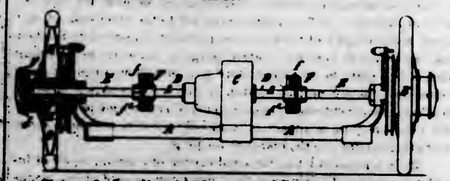


4. In an electrically-controlled musical instrument, the combination wth a plurality of magnetic controlling devices and a rail to support said devices, of a dynamo in circuit with said magnets, the field-casting of which constitutes a support for the rail.

5. In an electrically-controlled musical instrument, the combination with a plurality of magnetic controlling devices, a rail to support said devices and a drum, of a dynamo in circuit with the operating devices, the field-casting of said dynamo including an arm serving as a support for the rail and a hanger in which the drum is journaled.

6. In an electrically-controlled musical instrument controlled by a note-sheet, the combination with magnetic controlling devices and means to feed the note-sheet, of an electric machine capable of use either as a motor or as a generator of current, and connections whereby it may be used as a motor to drive the sheet-feeding means, a circuit including said machine and the magnetic controlling devices, a battery to supply current to run the motor and energize the controlling devices, a cut-out to disconnect the battery from said circuit, and means to operate the machine as a generator when the battery is disconnected from said circuit, for supplying current to the circuit which includes the magnetic controlling devices.

812,118. **DRIVING-AXLE FOR AUTOMOBILE VEHICLES.** JULES R. G. DESIS and LOUIS M. J. DE BOISSE, Paris, France. Filed June 14, 1904. Serial No. 212,519.



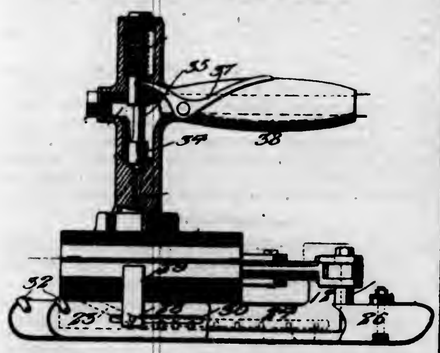
Claim.—1. In a live axle for automobile vehicles, the combination with a central shaft having a differential gear arranged thereon and toothed disks at the extremities of said shafts, of end shafts having internally-toothed drums meshing with said toothed disks, said end shafts also having toothed disks at their outer extremities, and

of internally-toothed drums secured to the road-wheels, said road-wheel drums engaging the toothed disks upon outer extremities of the end shafts.

2. A live axle for automobile vehicles, comprising a bridge, a central shaft, end shafts journaled in said bridge, said central shaft coupled to said end shafts, a differential gear upon said central shaft, a gear-case to said differential gear, said central shaft being journaled in said gear-case, a socket screwed into said gear-case, said socket being thereby adjustable in said gear-case, and a propeller-shaft journaled in said socket, said propeller-shaft having means for engaging and driving the differential gear.

3. A live axle for automobile vehicles comprising a bridge, tubular ends to said bridge, a central shaft, end shafts journaled in said tubular ends and coupled to said central shaft, road-wheels revolubly mounted upon said tubular ends, toothed connections between said road-wheels and said end shafts, a differential gear upon said central shaft, a gear-case to said differential gear, said gear-case being secured to the bridge and forming journals for said central shaft, a bevel-wheel mounted upon said differential gear, a socket screw-threaded into said gear-case so as to be adjustable therein, a propeller-shaft journaled in and passing through said screwed socket, and a bevel-pinion upon the inner end of the propeller-shaft, said pinion engaging said bevel-wheel and being adjustable for wear.

812,119. **SANDPAPERING-MACHINE.** ARTHUR B. DENISON, Beloit, Wis. Filed Nov. 30, 1904. Serial No. 234,201.



Claim.—1. In a device of the class described, a pair of cylinders, pistons arranged for reciprocation in the cylinders, polishing members connected to and for movement with the respective pistons, means for admitting air under pressure to the cylinders for operating the pistons, and a tubular member disposed between the polishing devices and having discharge-ports directed to the latter, said member being in communication with the cylinders and adapted to receive the exhaust from the latter.

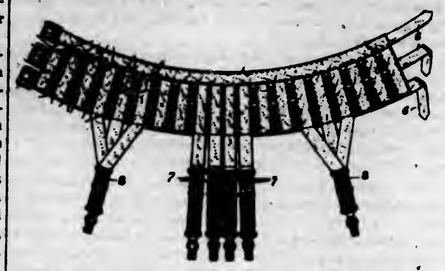
2. In a device of the class described, a pair of cylinders, pistons movable therein, polishing devices connected to and for movement with the respective pistons, means controlled by the movement of the pistons for admitting a fluid under pressure alternately to the cylinders, and a tubular exhaust member communicating with the cylinders and extended between the polishing devices, said member having discharge-ports for directing the exhaust fluid toward the polishing devices.

3. In a device of the class described, a pair of reversely-movable polishing devices, operating members connected therewith, a tubular member between the polishing devices and having discharge-ports directed toward the latter, and means for admitting fluid to and for actuating the operating members, the fluid being adapted to exhaust through the tubular member for preventing accumulations beneath the polishing devices.

4. In a device of the class described, a reciprocatory polishing device, a tubular member sustained adjacent the side thereof and provided with exhaust-ports directed toward the device, an operating member connected with said device, and means for admitting fluid under pressure to the operating member, and a tubular member for actuating the polishing device and preventing accumulations thereof beneath.

5. In a device of the class described, a movable polishing member, means for operating the same, a tubular member disposed and sustained at one side of the polishing device and having ports directed toward the latter, and means for admitting fluid under pressure through the member to prevent accumulations beneath the polishing device.

812,120. **COMBINED ABDOMINAL SUPPORT AND HOSE-SUPPORTER.** NELLIE L. DISNEY, Bridgeport, Conn. Filed Oct. 4, 1905. Serial No. 281,204.

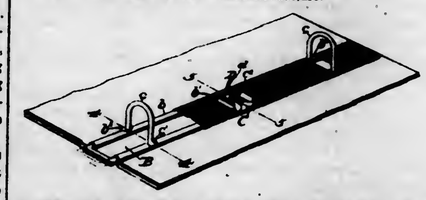


Claim.—1. A combined abdominal support and hose-supporter, comprising a waistband having depending therefrom the non-elastic flexible strips spaced apart, a plurality of elastic webbings spaced apart and crossing said strips, said webbings and strips being stitched together, suitable fastenings at the end of the support, and stocking-engaging members depending from said support.

2. A combined abdominal support and hose-supporter, comprising a waistband having depending therefrom the non-elastic flexible strips spaced apart, a plurality of elastic webbings spaced apart and crossing said strips at right angles whereby openings are provided between said webbings and strips, suitable fastenings at the ends of the support, and stocking-engaging members depending from the front and side portions of said support.

3. A combined abdominal support and hose-supporter, comprising vertically-disposed non-elastic strips and horizontally-disposed elastic webbings, which strips and webbings are spaced apart and cross each other and are secured together by stitching, suitable fastenings whereby the support may be secured around the waist of the wearer, and stocking-engaging members which depend from the lower edge of the support at the front and sides.

812,121. **TEMPORARY BINDER.** JOHN J. EDWARDS, Ann Arbor, Mich. Filed Mar. 16, 1906. Serial No. 306,433.



Claim.—1. A temporary or loose-leaf binder comprising a holder adapted for attachment to the back of a book-cover, a binding-wire hinged along one margin of the holder and provided with hooks extending across the body of the holder and having end portions constructed to engage with retaining means along the opposite margin of the holder for securing the hooks in closed position, and means along the latter margin adapted to engage and lock said end portions of the hooks.

2. A temporary or loose-leaf binder comprising a holder adapted for attachment to the back of a book-cover, a binding-wire having an intermediate portion rotatively secured to said holder along one margin thereof and rigid hooks at opposite extremities of said intermediate portion extending transversely of the holder to the opposite margin thereof, and means along the latter margin constructed to engage with the ends of said hooks for locking and holding them in closed position.

3. A temporary or loose-leaf binder comprising a holder adapted for attachment to the back of a book-cover, a binding-wire having an intermediate portion hinged along one margin of said holder and provided with rigid hooks and a projection extending transversely of the holder to the opposite margin thereof, and a locking

member slidably secured along said opposite margin adapted to en-

member slidably secured along said opposite margin adapted to engage said projection and positively lock and hold the hooks in closed position.

4. A temporary binder comprising a suitable holder, a hinged binding-wire having hooks, a projection extending from said binding-wire transversely of the holder in the same direction as the hooks, and a triple locking device consisting of a sliding member having notches or recesses therein to receive said hooks and tongue and adapted to be slid into engagement with said hooks and tongue and thereby firmly lock the binding-wire with the hooks in closed position, substantially as described.

5. A temporary binder for holding sheets and the like, comprising a holder adapted for attachment to the back of a book-cover, a binding-wire hinged longitudinally on said holder along one margin thereof and having lateral hooks extending transversely of the holder to its opposite margin for insertion through the sheets, and means adapted to engage said hooks for positively locking said wire with its hooks closed on the holder, substantially as described.

6. A temporary binder for holding sheets and the like, comprising a back plate or holder adapted for attachment to the back of a book-cover, a binding-wire hinged longitudinally along one margin of the holder and having lateral hooks extending transversely of the holder to its opposite margin for insertion through the sheets, and manipulative means on the latter margin of the back plate adapted to engage said hooks for positively locking said wire in position with its hooks closed or turned down on the back plate and for releasing said wire to permit turning thereof to open or raise the hooks and permit attachment or removal of the sheets, substantially as described.

7. A temporary binder comprising a back plate or holder, a binding-wire hinged longitudinally thereto having lateral hooks for insertion through the sheets and having a rigid lateral tongue, and a manipulative device on the holder adapted to engage said hooks and tongue to hold the hooks closed down on the holder and to release said hooks and tongue to permit opening or raising of the hooks, substantially as described.

8. A temporary binder comprising a back plate, a binding-wire having a hook and a locking member integral therewith, and means in the back plate for engaging said hook and locking member to lock the binding-wire in normal closed position, substantially as described.

9. A temporary binder comprising a back plate, a binding-wire having a portion pivotally secured in the back plate and provided with a hook, a tongue on the pivot portion, and means in the back plate adapted to engage said hook and tongue to prevent pivotal movement of the binding-wire, substantially as described.

10. A temporary binder comprising a back plate, a binding-wire having hooks at opposite ends and an intermediate pivot portion secured in the back plate and having a loop therein, a locking-slide in the back plate adapted to engage said hooks and loop to prevent pivotal movement of the binding-wire, and means for manipulating said slide, substantially as described.

11. A temporary binder comprising a back plate having a fold extending along one edge thereof forming a pivot-seat, a binding-wire having a hook and locking projection and a pivot portion secured in said seat, and means in the back plate coöperating with said projection to prevent pivotal movement of the binding-wire, substantially as described.

12. A temporary binder comprising a back plate, having its opposite edges folded, a binding-wire having a pivot portion secured in one of said folds and provided with a hook or hooks, a projection on the pivot portion, and a locking-slide secured in the other fold and movable along the back plate to engage said projection and prevent pivotal movement of the binding-wire, substantially as described.

13. A temporary binder comprising a back plate having its edges bent over upon itself longitudinally thereof so as to form a pivot-seat for the binding-wire and a slideway along the opposite edge thereof for a locking-slide, a binding-wire having a centrally-disposed projection and hooks at its ends rotatively supported in said pivot-seat, a slidable rod fitted in said slideway having notches or recesses therein confronting the ends of said hooks and projection when the hooks are closed upon the back plate, and notches or recesses in the edge of the back plate to receive the ends of said hooks, substantially as described.

14. A temporary binder for holding sheets of paper and the like, comprising a suitable holder independent of but adapted for attachment to the back of a book cover or support, and a binding-wire rotatively secured along one side of said holder and provided with hooks arranged to swing transversely of the holder and having their ends constructed to engage with retaining means at the opposite side or margin of the holder, together with means at the opposite side of the holder for engaging the ends of said hooks so as to retain them in closed position.

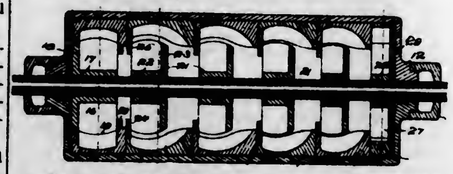
15. A temporary binder for holding sheets of paper and the like, comprising a holder independent of but adapted for attachment to a suitable support and consisting of an oblong plate having its opposite sides turned over upon itself or folded, a binding-wire rotatively secured in one of said folds and provided with hooks arranged to swing transversely of the holder to the opposite fold; said hooks having their ends constructed to coact with suitable retaining-means on the holder, and means at the latter fold or opposite side of the holder for engaging the ends of said hooks and retaining them in closed position.

16. A temporary or loose-leaf binder comprising an oblong holder having spaced openings or notches therein along one of its longer margins, a binding-wire hinged to said holder along its opposite margin, curved hooks extending from said binding-wire transversely of the holder having their ends adapted to enter said openings or notches, and means for engaging the ends of the hooks entered in said openings or notches to prevent the withdrawal thereof, substantially as described.

17. A temporary or loose-leaf binder comprising an oblong holder adapted for attachment to the back of a book-cover and having openings or notches along one margin thereof to receive the ends of hooks entered therein, a binding-wire rotatively secured on said holder and having a hook or hooks extending transversely thereof adapted to enter said openings or notches, said hooks having end portions constructed to engage retaining means within the holder, together with means for engaging said end portions and preventing the withdrawal of the hooks.

18. A temporary or loose-leaf binder comprising an oblong holder adapted for attachment to the back of a book-cover and having its longer marginal portions turned back upon itself or folded, and also having openings or notches along one of said longer margins, a binding-wire rotatively secured to said holder in one of said folds and having hooks arranged to extend across and enter the openings in the opposite fold, and means for engaging the ends of the hooks entering said openings to prevent the withdrawal thereof.

812,122. **GRINDING-MACHINE.** RILEY D. FASSETT, Denver, Colo., assignor of one-half to William H. Neff, Denver, Colo. Filed Dec. 3, 1904. Serial No. 235,574.



Claim.—1. In a machine of the character described, the combination with a series of rotatable beaters, of a series of stationary boxes surrounding said beaters and forming grinding-compartments, the internal diameters of said boxes diminishing from one end toward the other of said series, the external diameter of all of said boxes being equal, and each box having a series of pockets therein formed by integral ribs therebetween.

2. In a machine of the character described, the combination with a series of rotatable beaters, of a series of stationary boxes surrounding said beaters and forming grinding-compartments, the internal diameters of said boxes diminishing from one end toward the other of said series, and each of said boxes having a series of pockets therein, each pocket being of varying depth.

3. In a machine of the character described, the combination with a series of rotatable beaters, of a series of stationary boxes surrounding said beaters and forming grinding-compartments, the internal diameters of said boxes diminishing from one end toward the other of said series, and each box having a series of peripheral pockets therein forming ribs therebetween, each pocket having converging walls and being of varying depth.

4. In a machine of the character described, the combination with a series of beaters each comprising similarly-curved blades having irregular ends; of a series of stationary boxes surrounding the beaters and forming communicating grinding-compartments of different diameters, each box conforming in contour to the ends of the blades and having pockets therein.

5. In a machine of the character described, the combination with a series of rotatable beaters each comprising a hub, similarly-curved blades extending therefrom and having irregular ends, and means for connecting the blades at opposite edges; of a series of stationary boxes surrounding the beaters and forming grinding-compartments of different diameters, the inner surface of each box conforming in contour to the ends of the blades therein and having pockets forming ribs therebetween.

6. In a machine of the character described, the combination with a casing, of a series of rotatable beaters therein, each comprising a hub, similarly-curved blades extending therefrom and having irregular ends, and bracing means connecting the opposite edges of the blades, sectional boxes within the casing and surrounding the beaters, said boxes forming grinding-compartments and each box having an irregular working face conforming in contour to the ends of the blades.

7. In a machine of the character described, the combination with a casing comprising sections movably connected; of a series of rotatable beaters within the casing and each comprising a hub, similarly-curved blades, and bracing means connecting the edges of the blades, sectional boxes within the casing and surrounding the beaters, said boxes forming grinding-compartments of different diameters and having irregular inner faces conforming to the contour of the ends of the blades.

8. In a machine of the character described, the combination with a casing having an inlet and an outlet, of a series of rotatable beaters within the casing, and each comprising a hub, similarly-curved blades and strengthening devices connecting the edges of blades, means rotatable with the beaters for forcing material into engagement therewith, a discharge device within the casing having blades curved in a direction opposite to the blades of the beaters and a series of sectional boxes within the casing and surrounding the rotatable devices therein.

9. In a machine of the character described, the combination with a sectional casing, and means for securing the same in closed position; of a series of beaters rotatably mounted within the casing and each comprising a hub; similarly-curved blades having irregular working ends and bracing means connecting the blades, a series of sectional boxes within the casing and surrounding the beaters, said boxes having irregular working faces conforming in contour to the ends of the blades therein, means for forcing material into the boxes at one end and having blades curved in a direction opposite to those of the beaters, and a discharge device rotatably mounted within the casing.

10. In a machine of the character described, the combination with a sectional casing having an inlet and an outlet, and means for securing the same in closed position, of a shaft rotatably mounted in the casing, a series of rotatable beaters secured upon the shaft and each comprising a hub, blades having irregular working ends and bracing devices connecting the blades, a series of sectional boxes within the casing and surrounding the beaters, each of said boxes having an irregular working face conforming in contour to the ends of the blades, rotatable means adjacent the inlet for forcing material into the boxes, and a rotatable discharge device adjacent the outlet.

11. In a machine of the character described, the combination with a casing having an inlet and an outlet; of a rotatable shaft within the casing, a series of sectional boxes within the casing and forming grinding-compartments of different diameters, each of said boxes having an irregular working face, and end boxes within the casing and adjacent the inlet and outlet, each of said end boxes having an eccentric working face, a rotatable device within the inlet-box for forcing material into the adjoining boxes, a rotatable discharge device in the outlet-box, and a series of rotatable grinding devices in the grinding-compartments.

12. In a machine of the character described, the combination with a casing having an inlet and an outlet, a box within the casing and adjacent the inlet, said box having an eccentric working face, a rotatable feeding device within said box for drawing material through the inlet, said device comprising a hub and curved blades extending therefrom, a series of rotatable beaters within the casing each comprising a hub and similar blades curved in a direction opposite to those on the feeding device, sectional boxes within the casing and surrounding the beaters, said boxes being of different internal diameters and having irregular working faces and rotatable means for discharging material through the outlet.

13. In a machine of the character described, the combination with a series of rotatable beaters having blades with curved ends; of a series of stationary ribs surrounding each of said beaters to form a grinding chamber, said ribs conforming in contour to the ends of the blades and forming a continuous passage with waved walls.

14. In a machine of the character described, the combination with a series of rotatable beaters, having blades with curved ends; of a series of stationary ribs surrounding each of said beaters and conforming in contour to the ends of the blades, the series of ribs forming a passage having waved walls.

15. In a machine of the character described, the combination with a rotatable beater: of a stationary box surrounding the beater having ribs, said ribs forming pockets in the inner surface of said box, said pockets having overhanging walls.

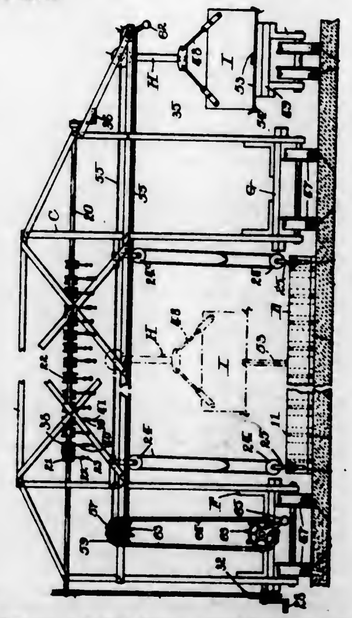
16. In a machine of the character described, the combination with a series of rotatable beaters having blades with curved ends, of a series of stationary boxes surrounding the beaters, said boxes being of different internal diameters and forming a continuous passage diminishing in diameter from one end to the other thereof, and ribs integral with the inner surfaces of the boxes, and conforming in contour with the ends of the blades, said ribs forming pockets therebetween of varying depths, said pockets having overhanging walls.

17. In a mechanism of the class described, the combination of a sectional casing, each section of said casing provided with a semicylindrical end portion, caps positioned upon the semicylindrical end portions of said sections, and grinding means positioned within said casing.

18. In a mechanism of the class described, the combination with a casing, of a rotatable beater positioned within said casing, said beater comprising a hub, similarly-curved blades extending from said hub, spacing means engaging said blades, and an intermediate short blade carried by said spacing means and positioned between each two of said similarly-curved blades.

19. In a mechanism of the class described, the combination with a casing, of a rotatable beater positioned within said casing, said beater comprising a hub provided with similarly-curved blades, spacing means engaging one side of each of said blades, and an intermediate blade positioned between each two of said similarly-curved blades and engaging said spacing means.

812,123. **MACHINE FOR MOLDING BUILDING-BLOCKS.** ALEXANDER A. FORBES, Duluth, Minn. Filed Mar. 31, 1905. Serial No. 253,033.



Claim.—1. A machine of the class set forth, comprising, in combination, a suitable base formed with a plurality of holders for mold-cores, mold-frame sides resting upon said base, mechanism above said base for lifting said sides and cores, and means for permitting said mechanism to be shifted.

2. A machine of the class set forth, comprising, in combination,

a traveler, a base below said traveler having a plurality of holders for mold-cores, a plurality of mold-frame parts on said base, and means carried by said traveler for raising said mold-frame parts and cores.

3. A machine of the class set forth, comprising, in combination, a traveler, a base below said traveler having means for holding a plurality of mold-frame parts together, and means carried by said traveler for raising said mold-frame parts.

4. A machine of the class set forth, comprising, in combination, a traveler, a base below said traveler having means for holding a plurality of mold-frame parts together, and means carried by said traveler for raising said mold-frame parts, and means for dumping the molding material out of said carrier.

17. A machine of the class set forth, comprising, in combination, a temporary mold-frame, a core, a base having means for hold-

said base, cores upon said holders, an overhead bridge, trucks below said bridge, a plurality of hoisting-drums carried by said bridge for raising said sides and cores, means for revolving said drums, means for holding said sides and cores in elevated position, a track upon

cular, with an annular cone-shaped depression in its outer face and a pivot-bolt opening through the center thereof, a channel formed in the edges of the flanges of the bases to register and so form an open-

a traveler, a base below said traveler having a plurality of holders for mold-cores, a plurality of mold-frame parts on said base, and means carried by said traveler for raising said mold-frame parts and cores.

3. A machine of the class set forth, comprising, in combination, a traveler, a base below said traveler having means for holding a plurality of mold-frame parts together, and means carried by said traveler for raising said parts.

4. A machine of the class set forth, comprising, in combination, a temporary mold-frame, a base for holding said mold-frame, overhead traveling mechanism adapted to separate said frame from said base, and a carrier on said traveling mechanism.

5. A machine of the class set forth, comprising, in combination with a mold frame and core, said frame having a pair of longitudinal detachable sides, a parting-wall between said sides, transverse division sides arranged in pairs across the spaces between the longitudinal sides and parting-wall to divide the same into a plurality of molds and means for permitting the transverse division sides to collapse, a base, means for holding the parts of said frame and core on said base, a traveler, and means on said traveler for withdrawing the parts of said frames.

6. A machine of the class set forth, comprising, in combination, a temporary mold-frame, a base below said frame, a bridge above said frame, means for supporting the ends of said bridge, means carried by said bridge for separating said frame and base, a carrier, and means for moving said carrier upon said bridge.

7. A machine of the class set forth, comprising, in combination, a temporary mold-frame forming a plurality of molds, a base below said frame, means for separating said frame and base and carrying the parts removed away from the molded blocks, and means for carrying molding material to said molds.

8. A machine of the class set forth, consisting, in combination, of a traveler, a base, below said traveler, provided with means for holding mold-cores, a frame, surrounding said cores, adapted to form a plurality of molds on said base, means on said traveler for lifting said frame, means also on said traveler for lifting said cores, and a carrier coöperating with said traveler for conveying molding material to said frame.

9. A machine of the class set forth, consisting, in combination, of a traveler, a base below said traveler, mold-frame sides on said base, means for detachably holding said sides together on said base to form a mold, means on said traveler for removing said sides, and a carrier movable upon said traveler for molding material.

10. A machine of the class set forth, consisting, in combination, of a base having means for holding a mold-frame, a traveler having means for permitting the same to be shifted above said base, means on said traveler for lifting said mold-frame, means for holding said mold-frame in superior position, and means coöperating with said traveler for carrying molding material to said mold-frame.

11. A machine of the class set forth, consisting, in combination, of a mold-frame, a base adapted to support, and formed with a core-holder in, said frame, a traveler for removing said frame from said base, means for permitting said frame to be returned to said base, and a carrier coöperating with said traveler for conveying molding material to said frame.

12. A machine of the class set forth, consisting, in combination, of a traveler, a base below said traveler, a mold-frame resting on said base, means carried by said traveler for engaging and lifting said mold-frame, means for holding said mold-frame in superior position, and means on said traveler for conveying molding material to said frame.

13. A machine of the class set forth, consisting, in combination, of a traveler, a base below said traveler, a mold-frame, means on said base for holding said mold-frame, means carried by said traveler for lifting parts of said mold-frame, a carrier, and means for moving said carrier on said traveler.

14. A machine of the class set forth, consisting, in combination, of an overhead traveler, a base below said traveler, mold-frame sides and cores on said base, means on said base for holding said sides and cores to form a mold, means on said traveler for removing said sides and cores, a carrier, and means for moving said carrier on said traveler.

15. A machine of the class set forth, comprising, in combination, a temporary mold-frame, a base, means for holding the parts of said mold-frame on said base, a traveler above said base, means for lifting the parts of said mold-frame on said traveler, and a carrier for molding material on said traveler.

16. A machine of the class set forth, comprising, in combination, a temporary mold-frame, a base for holding said mold-frame, a traveler above said mold-frame, means on said traveler for removing said mold-frame, a carrier, means for moving said carrier above said mold-frame, and means for dumping the molding material out of said carrier.

17. A machine of the class set forth, comprising, in combination, a temporary mold-frame, a core, a base having means for holding said frame and core, a traveler having means to permit the same being moved above said base, means on said traveler for removing said frame and core, a carrier on said traveler, and means for moving said mold-frame above said base.

18. A machine of the class set forth, comprising, in combination, a temporary mold-frame, a base for holding said mold-frame, a carrier above said base, means for moving said carrier, a bucket, and means for detachably holding said bucket on said carrier.

19. A machine of the class set forth, comprising, in combination with a temporary mold frame and core, a base having means for holding said frame and core, a traveler having means to permit the same being moved above said base, means on said traveler for lifting said frame and core, a carrier, means for moving said carrier on said traveler, a bucket, means for detachably connecting said bucket to said carrier, and means for emptying said bucket.

20. A machine of the class set forth, comprising, in combination, a temporary mold-frame, a base having means for holding said frame, a traveler having means to permit the same being moved above said mold-frame, means on said traveler for lifting said frame, a carrier, a track on said traveler, and means for moving said carrier upon said track.

21. A machine of the class set forth, comprising, in combination, a temporary mold-frame, a base having means for holding said frame, a traveler above said base, means on said traveler for lifting the parts of said frame, a carrier, and a track upon which said carrier is adapted to move upon said traveler.

22. A machine of the class set forth, comprising, in combination, a temporary mold-frame, a base for holding said mold-frame, a traveler above said mold-frame, means on said traveler for removing said mold-frame, a carrier, and means for moving said carrier.

23. A machine of the class set forth, comprising, in combination with a base provided with means for holding the parts of a mold-frame, sides and a core forming said mold-frame, a bridge above said mold-frame, a truck under each end of said bridge, and means on said bridge for lifting and holding said sides and core suspended, for the purposes specified.

24. A machine of the class set forth, comprising, in combination with a base formed with means for holding the parts of a mold-frame, detachable sides adapted to form a mold, trucks adapted to move on said base, an overhead bridge between said trucks and above said mold-frame, and means carried by said overhead bridge for raising said sides and for carrying molding material to said mold-frame.

25. A machine of the class set forth, comprising, in combination with a base, a mold-frame upon said base, an overhead bridge above said mold-frame, trucks for supporting said bridge, means carried by said bridge for raising said mold-frame, and a carrier on said bridge for molding material.

26. A machine of the class set forth, comprising, in combination with a base, a mold-frame upon said base, an overhead bridge above said mold-frame, trucks below said bridge, shafts carried by said bridge, drums upon said shafts, cables carried by said drums for lifting said mold-frame, and means for revolving said shafts.

27. A machine of the class set forth, comprising, in combination with a suitable base, sides on said base adapted to form a mold, an overhead bridge, trucks below said bridge, tracks upon said base upon which said trucks are adapted to run, a plurality of hoisting-drums on said frame for raising the sides of said mold-frame, and means for revolving said drums and holding said sides elevated.

28. A machine of the class set forth, comprising, in combination with a suitable base, sides on said base adapted to form a mold-frame, an overhead bridge, trucks below said bridge, tracks upon which said trucks are adapted to run, a plurality of hoisting-drums upon said bridge, means for revolving said drums and for holding said sides in elevated position, a carrier upon said bridge, and a bucket upon said carrier.

29. A machine of the class set forth, consisting, in combination with a suitable base formed with core-holders, of mold-frame sides on said base, cores upon said holders, an overhead bridge above said mold-frame sides, trucks below said bridge, hoisting-drums upon said bridge for raising said mold-frame sides and cores, means for revolving said drum, and means for holding said sides and cores in elevated position.

30. A machine of the class set forth, consisting, in combination, of a suitable base formed with core-holders, mold-frame sides upon said base, cores upon said holders, an overhead bridge, trucks below said bridge, a plurality of hoisting-drums carried by said bridge for raising said sides and cores, means for revolving said drums, means for holding said sides and cores in elevated position, a track upon said bridge, a carrier adapted to travel upon said track over the mold-frame, and means for moving said carrier.

31. A machine of the class set forth, consisting, in combination with a base formed with core-holders, of mold-frame sides on said base, cores between said sides and on said holders, an overhead bridge, trucks below said bridge, a track upon said bridge, and a carrier for molding material adapted to travel upon said track.

32. A machine of the class set forth, consisting, in combination with a suitable base formed with core-holders, of mold-frame sides resting upon said base, cores between said sides and on said holders, an overhead bridge, trucks below said bridge, a track on said bridge, a carrier for molding material adapted to travel upon said track, and means for moving said carrier.

33. A machine of the class set forth, comprising, in combination with a suitable base formed with core-holders, mold-frame sides on said base, cores between said sides and on said holders, an overhead bridge, trucks below said bridge, a track on said bridge, a carrier adapted to travel upon said track, means for moving said carrier, a detachable bucket on said carrier, and a truck below said bucket adapted to support the same when detached from said carrier.

34. A machine of the class set forth, consisting, in combination with a suitable base formed with core-holders, mold-frame sides on said base, cores between said sides and on said holders, an overhead bridge, trucks below said bridge, means carried by said bridge for raising said sides and cores and for holding them in elevated position, a track carried by said bridge, a carrier adapted to travel on said track, a detachable bucket on said carrier, means for moving said carrier, a truck adapted to support said bucket when detached from said carrier, and parallel tracks on said base for all of said trucks to run upon.

812,124. **FORMALDEHYDE HYDROSULFITE AND PROCESS OF MAKING SAME.** EMILE A. FOURNEAUX, New York, N. Y., assignor to Hermann A. Metz, New York, N. Y. Filed Mar. 30, 1905. Serial No. 253,267.

Claim.—1. The process of making basic zinc formaldehyde hydrosulfite (S) which consists in reacting with a suitable alkali compound upon a solution of zinc hydrosulfite treated with formaldehyde, substantially as described.

2. As a new article of manufacture, basic zinc formaldehyde hydrosulfite (S) occurring as a white crystalline precipitate, capable of being dried on the water-bath in the open air without decomposing, and one part capable of reducing about one and one-half parts of pure indigo in the form of indigo sulfonic acid, substantially as described.

3. The process of making alkali formaldehyde hydrosulfite (S) which consists in reacting with a suitable alkali compound upon the basic zinc formaldehyde hydrosulfite (S), substantially as described.

4. The process of making sodium formaldehyde hydrosulfite (S) which consists in reacting with sodium carbonate upon basic zinc formaldehyde hydrosulfite (S), substantially as described.

5. The process which consists in reacting with a suitable alkali compound upon a solution of zinc hydrosulfite treated with formaldehyde, thereby forming basic zinc formaldehyde hydrosulfite (S), and then reacting with a suitable alkali compound upon said basic zinc formaldehyde hydrosulfite (S) to form alkali-formaldehyed hydrosulfite (S), substantially as described.

812,125. **TELEPHONE-TRANSMITTER ARM.** WILLIAM D. GEAREY, Philadelphia, Pa. Filed Mar. 7, 1901. Serial No. 50,366.

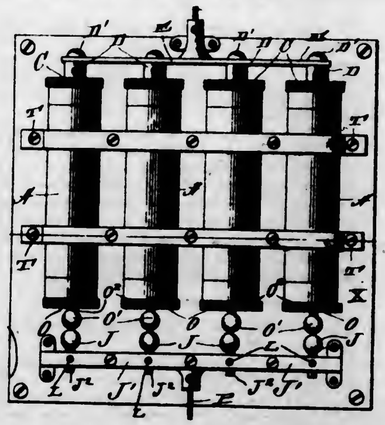
Claim.—1. A telephone-transmitter support comprising a base having spring cheek-plates, means to secure said base horizontally, and an arm secured to said base, comprising the following instrumentalities: two twin castings each concave on one side, with enlarged heads and bases, each head being also concave and the two heads when put together forming a circular cup, a threaded thimble secured to said cup, a spring-contact supported in but insulated from the cup and thimble, the base of each casting being substantially circular, with an annular cone-shaped depression in its outer face and a pivot-bolt opening through the center thereof, a channel formed in the edges of the flanges of the bases to register and so form an opening for passing the conductor-cords, the axis of said opening being approximately parallel to the face of the supporting base-plate, and a conductor led from the contact-thimble through the arm and the said opening, where it emerges above the base in every position of the arm, substantially as described.

2. In a telephone-transmitter arm the combination of the pair of mate castings having registering concave inner faces, a supporting-base, an opening for passage of conductors in the heel or pivot end of the arm, a projecting flange or boss surrounding said opening in whole or in part, and a pivot-bolt securing the arm on the base, whereby the said boss or flange acts as a stop against the base, and prevents breaking or damaging the conductors by turning the arm too far up or down, substantially as described.

3. A telephone-transmitter support comprising a base having spring cheek-plates, means to secure said base horizontally, and an arm secured to said base, comprising the following instrumentalities: two twin castings each concave on one side, with enlarged heads and bases, each head being also concave and the two heads when put together forming a circular cup, a threaded thimble secured to said cup, a spring-contact supported in but insulated from the cup and thimble, the base of each casting being substantially circular, with an annular cone-shaped depression in its outer face and a pivot-bolt opening through the center thereof, a channel formed in the edges of the flanges of the bases to register and so form an opening for passing the conductor-cords, the axis of said opening being approximately parallel to the face of the supporting base-plate, with a projecting flange or boss to serve as a stop against the same and limit the motion of the arm, a pair of cone-washers with flat bases against the inner faces of the cheek-plates and cones in the arm-base depressions, and a pivot-bolt extending through cheek-plates, cone-washers and arm-bases, substantially as described.

4. A telephone-support comprising a base having cheek-plates, an arm composed of two twin concave members having their butt-ends held together between the cheek-plates, and turning on annular faces thereon; the outer or transmitter-carrying ends of the arm members being expanded so that when put together they constitute a cup, a circular transmitter-support secured within said cup, and means for securing the two halves of the arm around and to said transmitter-support, whereby they are held together, substantially as described.

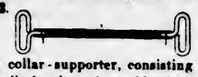
812,126. **LIGHTNING-ARRESTER.** WILLIAM GIFFORD, Thompsonville, Mich., assignor of one-half to E. M. DIXON, Thompsonville, Mich. Filed May 23, 1905. Serial No. 261,277.



Claim.—A lightning-arrester comprising a series of insulating-tubes adapted to hold a non-inductive material, metallic caps fitted to the ends of said tubes, a bar connected to corresponding caps, a binding-post projecting from said bar and a line-wire connected to said post, means for holding said bar to the caps, a series of plugs having shank portions fitted to the caps at the lower ends of the tubes, a bar having set-screws therein, balls having shank portions passing through apertures in the bar carrying said set-screws and held in ad-

justed positions by the latter, a ground-wire connected to said set-screw-carrying bar, a carbon resting upon each bottom of the tubes, and a carbon disk having a threaded shank portion, fitting within a threaded opening in each cap at the tops of the tubes, said shank portion of the carbon disk being surrounded by an air-space, as shown and described.

812,127. COLLAR-SUPPORTER. OLIVER G. GOODMAN and BRADFORD L. GOODMAN, Birmingham, England. Filed Aug. 14, 1905. Serial No. 274,223.



Claim.—1. A collar-supporter, consisting of a flexible stem formed by a close coil of spring-wire and having means for its attachment at the opposite ends, substantially as set forth.

2. A collar-supporter consisting of a flexible stem formed from a close coil of spring-wire, and attachment-loops or eyes having shanks which are inserted into and secured with the ends of the said stem, substantially as set forth.

812,128. LIFTING-JACK. WILLIAM H. GRIFFITH, Worthington, Ind. Filed Jan. 18, 1905. Serial No. 241,067.

Claim.—1. The combination with a lifting-jack, of a supplemental jaw arranged and adapted to coöperate with the movable parts of the lifting-jack whereby to form a vise.

2. The combination with the bar or standard of a lifting-jack, and runners mounted thereon, with means for automatically gripping the runners to the bar or standard, of a supplemental jaw mounted on the bar or standard and adapted to coöperate with one of the runners whereby to transform the jack into a vise.

3. The combination with a base, and a bar or standard pivotally supported thereon, of runners mounted on the bar or standard, means for locking them thereto, and a supplemental jaw adapted to be employed to coöperate with the runner whereby the lifting-jack may be transformed into a vise.

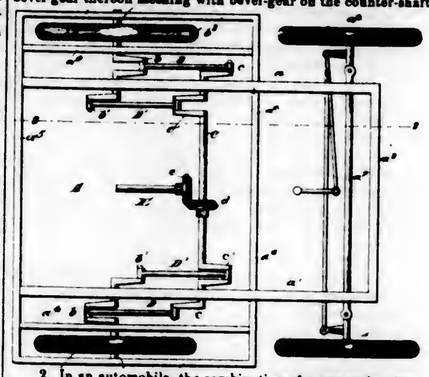
4. The combination with the bar or standard of a lifting-jack, of a runner having a V-shaped chamber therein located directly beneath the load, a wedge-shaped block fitted to said chamber and carrying a grip-block, and a cam-lever for forcing said V-shaped block in one direction.

5. The combination with a bar or standard, of a runner having a V-shaped chamber therein located directly beneath the load, a wedge-shaped block fitted to said chamber and carrying a grip-block, a spring for moving said wedge-shaped block into position to cause the grip-block to lock the runner to the bar or standard, and means for releasing said block therefrom.

6. The combination with a bar or standard, of a runner mounted to slide thereon and provided with a V-shaped chamber located directly beneath the load, a wedge-shaped block fitted therein, a grip-block carried by the wedge-shaped block, a spring for normally raising the wedge-shaped block, the runner having a diagonally-disposed slot therein, a pin extending through this slot from the block, cam-lever mounted on the pin and adapted to engage a shoulder on the runner whereby to force the block against the action of the spring and release the runner from the bar or standard.

812,129. AUTOMOBILE. BEN B. HERVEY, Spokane, Wash. Filed Aug. 15, 1905. Serial No. 274,396.

Claim.—1. In an automobile, the combination of a supporting-frame comprising relatively long longitudinal bars, connected at their front ends by a cross-bar, spaced pairs of relatively short longitudinal bars arranged without the relatively long bars at the rear ends thereof and spaced apart therefrom, the cross-bars connecting the ends of the pairs and the relatively long bars, an axle fixed on the front ends of the relatively long bars, wheels on the ends of the axle, alined shafts having oppositely-disposed crank-arms journaled on the pairs of bars and on the relatively long bars, and with a crank-arm on either side of said long bars, wheels on the shafts between the members of the pairs of bars, a counter-shaft journaled in front of the shafts and provided at either end with oppositely-disposed crank-arms arranged on either side of the long bars, connecting-rods between the corresponding crank-arms, a bevel-gear on the counter-shaft, a power-shaft journaled longitudinally on the frame and a bevel-gear thereon meshing with bevel-gear on the counter-shaft.



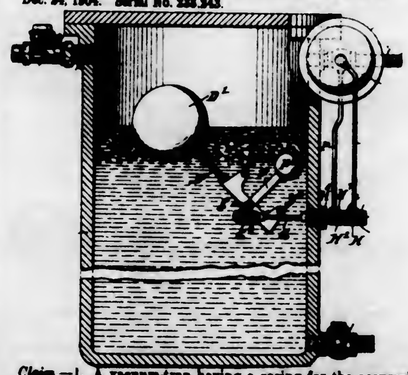
2. In an automobile, the combination of a supporting-frame, a plurality of shafts having oppositely-projecting crank-arms journaled in the frame, wheels on the shafts, a counter-shaft journaled in the frame and provided at either end with crank-arms corresponding to the crank-arms of the first-named shaft, connecting-rods between the corresponding crank-arms, a bevel-gear on the counter-shaft, and a power-shaft journaled longitudinally of the frame and provided with a bevel-gear meshing with the bevel-gear on the crank-shaft.

3. In an automobile, the combination of a supporting-frame, a plurality of alined shafts journaled in the frame, wheels on the shafts, a counter-shaft journaled in the frame, oppositely-arranged driving connections between each of the alined shafts and the counter-shaft, a power-shaft, and connections between the power-shaft and the counter-shaft.

4. In an automobile, the combination of a supporting-frame, a plurality of alined shafts journaled in the frame, and provided with oppositely-projecting crank-arms, wheels on the shafts, a counter-shaft journaled in the frame and provided at either end with crank-arms corresponding to the crank-arms of the alined shafts, connections between the corresponding arms, a power-shaft, and connections between the power-shaft and the counter-shaft.

5. In an automobile, the combination of a supporting-frame, comprising relatively long longitudinal bars, spaced pairs of relatively short longitudinal bars arranged without the long bars at the rear ends thereof and spaced apart therefrom, cross-bars connecting the longitudinal bars, wheels journaled on either side of the frame between the members of the respective pairs of bars and means whereby to drive the wheels.

812,130. VACUUM-TRAP. GEORGE M. HILGER, Chicago, Ill. Filed Dec. 24, 1904. Serial No. 238,243.



Claim.—1. A vacuum-trap having a casing for the accumulation of the liquid, a connection with a pressure-supply and a vacuum apparatus, a valve mechanism in the said connection, for alternately connecting the casing with the pressure-supply and the vacuum apparatus, a fluid-pressure device for actuating the said valve mechanism, and a float-controlled valve for alternately connecting the said fluid-pressure device with the said vacuum apparatus and the atmosphere.

2. The combination with a casing, of a valve mechanism, a float-lever carrying a float acted on by the liquid accumulating in the casing, the said float-lever being provided with projections on the same side of the lever at opposite sides of its fulcrum, a weighted lever mounted to swing on the fulcrum of the float-lever, and extending between the said projections on the float-lever, the said projections being adapted to alternately engage opposite sides of said weighted lever, and a slotted link engaged by the said weighted lever and connected with the said valve mechanism.

3. The combination with a device to be controlled, of a weighted lever connected with the said device, and a float-lever carrying a float, and provided with two projections extending from the same side of the lever and located at opposite sides of the fulcrum, the said projections being adapted to alternately engage opposite sides of the said weighted lever.

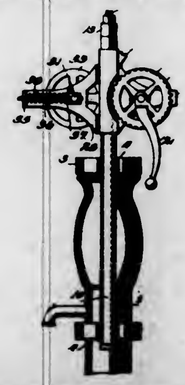
4. The combination with a diaphragm-casing, and a spring-pressed diaphragm therein, of a valve-casing having connection with the apparatus to be controlled, a connection with a pressure-supply, a connection with a vacuum-producing device, and valves controlled by the said diaphragm, for alternately connecting the said apparatus connection with the pressure-supply and the vacuum-producing apparatus.

5. The combination with a diaphragm-casing, and a spring-pressed diaphragm therein, of a valve-casing having connection with the apparatus to be controlled, a connection with a pressure-supply, a connection with a vacuum-producing device, valves controlled by the said diaphragm, or alternately connecting the said apparatus connection with the pressure-supply and the vacuum-producing apparatus, and a float-controlled valve having connection with the pressure side of the diaphragm and with the said vacuum connection.

6. The combination with a liquid receiving and discharging casing having an inlet and a discharge for the liquid, a valve mechanism, a float-controlled device connected with the said valve mechanism, a valve-casing having connection with the said liquid receiving and discharging casing, a connection with a pressure-supply, a connection with a vacuum-producing device, a spring-pressed diaphragm alternately connected by the said valve mechanism with the atmosphere and the said vacuum-producing connection, and valves in the said valve-casing, controlled by the said diaphragm.

7. A vacuum-trap comprising a casing for the accumulation of the liquid, a connection between the said casing and a pressure-supply and a vacuum apparatus, a valve mechanism in the said connection, for alternately connecting the casing with the pressure-supply and the vacuum apparatus, a diaphragm-casing, a spring-pressed diaphragm therein connected with the valve mechanism to actuate the latter, and a float-controlled valve for alternately connecting the diaphragm-chamber with the atmosphere and the vacuum apparatus.

812,131. PUMP-ROD EJECTOR. WILLIAM HOBENSTRA, Harrison, S. D. Filed Sept. 3, 1905. Serial No. 276,804.



Claim.—1. In a device of the character described, the combination with a pump-rod, of a standard, pump-rod-engaging means carried by the standard, and means for moving the pump-rod-engaging means upwardly to eject the pump-rod.

2. In a device of the character described, the combination with a pump-rod, of a standard, a member movably mounted upon the standard, means carried by said member to engage the pump-rod, and means for moving the member upward to eject the pump-rod.

3. In a device of the character described, the combination with a pump-rod, of a standard, a rack-bar movably mounted thereon, means carried by the rack-bar to engage the pump-rod, a cog-wheel, and means for turning the cog-wheel to raise the standard to eject the pump-rod.

4. In a device of the character set forth, the combination with a pump-rod, of a standard, a member movably mounted thereon, means carried by said member to engage the pump-rod, guiding means carried by the standard, and means for raising said member vertically to eject the pump-rod.

5. In a device of the character described, the combination with a pump-rod, of a standard, a member movably mounted thereon, means carried by the member to engage the pump-rod, pulleys carried by the standard to guide the pump-rod as it is being ejected, and means to move the member vertically to eject the pump-rod.

6. In a device of the character described, the combination with a pump-rod, of a standard, a member movably mounted thereon, means carried by the member to engage the pump-rod, a bracket fixed to the standard, a shaft carried by said bracket, a pulley mounted upon said shaft, means carried by the shaft to engage the member to the bracket secured to the standard, and a pulley yieldingly mounted on said last-named bracket.

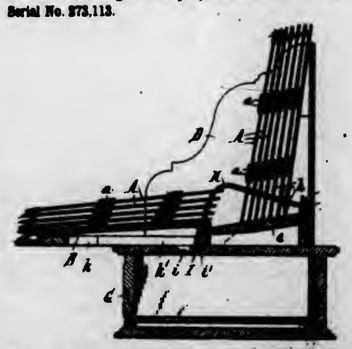
7. In a device of the character described, the combination with a pump-rod, of a standard, a rack-bar movably mounted thereon, means carried by the rack-bar to engage the pump-rod, a bracket secured to the standard, a shaft carried by said bracket, a pulley mounted on said shaft, a cog-wheel mounted on said shaft and adapted to engage the rack-bar, another bracket secured to the standard, and a pulley yieldingly mounted on said last-named bracket.

8. In a device of the character described, the combination with a pump-rod, of a standard, means carried by the standard for ejecting the pump-rod, and a yielding member to guide the pump-rod as it is being ejected.

9. In a device of the character described, the combination with a pump-rod, of a standard, means carried by the standard for ejecting the pump-rod, a pulley journaled in fixed bearings, and a pulley yieldingly journaled, said pulleys serving to guide the pump-rod as it is being ejected.

10. In a device of the character described, the combination with a pump-rod, of a standard, means carried by the standard for ejecting the pump-rod, a pulley journaled in fixed bearings, another pulley journaled in yielding bearings and pivotally mounted, said pulleys serving to guide the pump-rod as it is being ejected.

812,132. FILE. JOHN F. HUBER, Lockport, N. Y., assignor to Huber Account Register Company, Buffalo, N. Y. Filed Aug. 7, 1905. Serial No. 273,113.



Claim.—1. The combination of a holder, a series of movable leaves thereon, and one or more flexible extensible connecting members attached to said holder and having sliding connections with said leaves, whereby the connecting member or members can move relative to said leaves in the direction of the planes thereof, substantially as set forth.

2. The combination of a holder, a series of movable leaves thereon, and one or more flexible elastic connecting members attached to said holder and passing through elongated slots in said leaves,

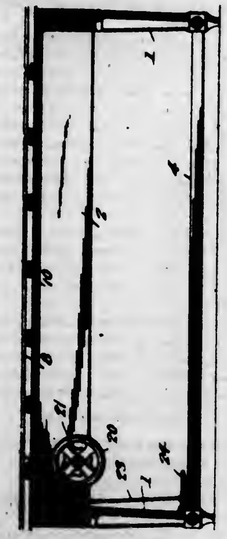
whereby the connecting member or members can move relative to said leaves in the direction of the planes thereof, substantially as set forth.

3. The combination of a holder, a series of movable leaves thereon, and one or more flexible extensible connecting members detachably secured to said holder and having sliding connections with said leaves whereby the connecting member or members can move relative to said leaves in the direction of the planes thereof, substantially as set forth.

4. The combination of a holder, a series of movable leaves thereon, flexible elastic connecting members passing through elongated slots in said leaves, cross-bars attached to the opposite ends of said connecting members, and means for detachably securing said cross-bars to said holder, substantially as set forth.

5. The combination of a holder, a slotted sliding shelf therein, a series of movable leaves on said holder, and one or more flexible extensible connecting members attached to said holder and having sliding connections with said leaves, said connecting member or members passing through the slot or slots of said shelf, substantially as set forth.

812,133. SURGICAL TABLE. THOMAS J. JAMES, ROBERT MCALLISTER, and WILLIAM S. BYRAM, Minneola, Mont. Filed June 3, 1905. Serial No. 263,622.



Claim.—1. In a surgical table, a frame, a top comprising a plurality of sections, a rotary head, operative connections between the head and a pair of sections, a winding-shaft, and a flexible connecting element between the head and shaft, the latter being operable for imparting movement through the head and connections to the sections.

2. In a surgical table, a frame, a top comprising a plurality of sections, a rotary drum, link connections between the drum and a pair of the sections, a belt normally wound on the drum, and means for unwinding the belt to rotate the drum and through the intermediate connections impart movement to the sections.

3. In a surgical table, a frame, a top comprising a plurality of sections, devices engaging and designed to support the end sections in folded position at the ends of the frame, and mechanism connected with a pair of the other sections for moving the latter from each other upon the frame.

4. In a surgical table, a frame, a top comprising a plurality of sections, rollers carried by a pair of said sections and adapted for travel on the frame, and mechanism operatively connected with said pair of sections and operable for moving the latter from each other.

812,134. SHADE-ROLLER. WILLIAM D. JAMES, Saginaw, Mich., assignor to Cumber Shade Roller Company, Bay City, Mich. Filed Oct. 9, 1903. Serial No. 176,811.

Claim.—1. The combination with a shade-roller spring and a spindle, of a bung having a reduced and recessed end; a metal cup inserted in the reduced and recessed end of said bung, to receive the spindle of the said shade-roller, substantially as described.

2. The combination in a shade-roller, with a spindle and a spring, of a bung fixed in the roller, a hollow support projecting from the bung and adapted to receive one end of the spindle, the spring surrounding the projecting support, and a strengthening means received within the projecting support to form a seat for the end of the spindle.

3. The combination with a shade-roller provided with a spindle, spring and bung, of a hollow nose carried by the bung and surrounded by the spring, the tendency of which spring is to compress the nose, one end of the spindle received in the hollow nose and a hollow reinforcing member seated in the nose and inclosing the end of the spindle, the member preventing a compression of the nose upon the end of the spindle.

812,135. MANUFACTURE OF HOLLOW METALLIC BALLS FROM SHEET METAL. ALLEN JOHNSTON, Ottumwa, Iowa. Original application filed Apr. 4, 1903. Serial No. 151,419. Divided and application filed Aug. 21, 1903. Serial No. 170,371. Again divided and this application filed Mar. 3, 1905. Serial No. 248,310.

Claim.—1. The process of making hollow metallic balls from sheet-metal blanks by stamping said blank into the shape of a cup having a rounded bottom and a serrated rim, and then closing the cup and swelling or expanding the same to form a ball of larger diameter than the cup.

2. The process of making hollow metallic balls from a strip of metal by first severing a piece to form a rectangular blank, stamping it into the shape of a cup having a rounded bottom and a serrated rim, and then closing the cup and simultaneously swelling or expanding the same to form a ball of larger diameter than the cup.

3. The process of making hollow metallic balls from a strip of metal by first severing a piece to form a rectangular blank, stamping it into the shape of a cup having a rounded bottom and a serrated rim, and then closing the cup and swelling or expanding the same to form a ball of larger diameter than the cup.

4. The process of making hollow metallic balls from sheet metal by first forming a rectangular blank, stamping it into the shape of a cup having a rounded bottom and a serrated rim, and then closing the cup and swelling or expanding the same to form a ball of larger diameter than the cup.

5. The process of making hollow metallic articles from sheet-metal blanks by stamping said blank into the shape of a cup, and then closing the cup and swelling or expanding the same to form an article of larger diameter than the cup.

6. The process of making hollow metallic articles from sheet-metal blanks by stamping said blank into the shape of a cup, and then closing the cup and simultaneously swelling or expanding the same to form an article of larger diameter than the cup.

7. The process of making hollow metallic articles from sheet-metal blanks by stamping said blank into the shape of a cup, having a serrated rim, and then closing the cup and swelling or expanding the same to form an article of larger diameter than the cup.

8. The process of making a hollow metallic article from a rectangular sheet-metal blank by stamping or drawing said blank into the shape of a cup having a closed bottom and a serrated rim, the edges of the points or apices of said rim being convexly curved, and then closing the open end of the cup.

9. The process of making a hollow metallic ball from a rectangular sheet-metal blank by stamping or drawing said blank into the shape of a cup having a rounded bottom and a serrated rim, the edges of the points or apices of said rim being convexly curved, and then closing the open end of the cup to form a sphere.

10. The process of making a hollow metallic ball from a square sheet-metal blank by stamping or drawing said blank into the shape of a cup having a rounded bottom and a serrated rim, the edges of the points or apices of said rim being convexly curved, and then closing the open end of the cup to form a sphere.

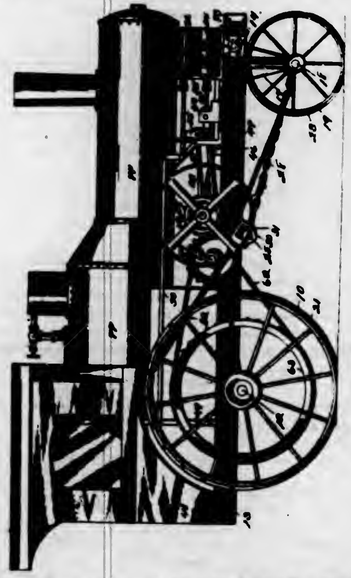
11. The process of making a hollow metallic ball from a square sheet-metal blank by stamping or drawing said blank into the shape of a cup having a rounded bottom and a serrated rim, the edges of the points or apices of said rim being convexly curved, and then closing the cup and swelling or expanding the same to form a ball of larger diameter than the cup.

812,136. SASH-HOLDER. ANDREW A. JONES, Cincinnati, Ohio. Filed May 18, 1905. Serial No. 261,064.

Claim.—1. In a window-sash tightener, a dog, adapted to be pivoted in the side strip of the window-sash, a hollow head on said dog, a foot extending from said dog, a sash-cord extending into said hollow head, means for holding said sash-cord in place in said hollow head, in combination with a sash-weight for tilting said dog to impinge against the parting-strip of the window-frame, as and for the purposes set forth.

2. In a window-sash tightener, a dog, adapted to be pivoted in side strip of the window-sash, a hollow head on said dog, a foot, extending from said dog, a sash-cord extending into said hollow head, a plate covering said hollow head and screwed in place, in combination with a sash-weight for tilting said dog to impinge against the parting-strip of the window-frame, as and for the purposes set forth.

812,137. TRACTION-ENGINE. WILBUR S. KELLEY, Newton, Iowa, assignor of one-half to Charles C. Kooper, Newton, Iowa. Filed Oct. 17, 1904. Serial No. 228,334.



Claim.—1. In an engine, a frame formed of channel-iron bent on opposite sides of its center and having its end portions extended in parallel lines, a steering-truck supporting the closed forward end portion of said frame, a traction-truck supporting the rear open end portion of said frame, an engine and driving mechanism mounted on said frame, detachable connections between said driving mechanism and the traction-truck, a boiler mounted on said frame independent of the engine and driving mechanism, a hoisting-shaft mounted transversely of the forward end portion of said frame, a cable on said shaft, and detachable connections between said hoisting-shaft and the driving mechanism.

2. In a traction-engine, a supporting-frame formed with an aperture in one end, guide-rollers opposite each other and extending into said aperture, a drum-shaft mounted transversely of said frame adjacent said aperture and parallel with said rollers, a cable on said shaft and extending through said aperture between said rollers, and means for driving said shaft.

3. In a traction-engine, a rigid frame, trucks supporting said frame, a pillow-block on said frame, a boiler supported on said pillow-block and frame, engine-beds supported on said frame independent of the boiler, engines supported on said beds independent of the boiler, fraction mechanism on said frame independent of the boiler, driving mechanism mounted on said frame independent of the boiler, and adapted to be connected to the traction mechanism at times and to the machine to be driven at times, and connections between said engines and said driving mechanism.

4. In a traction-engine, a rigid frame, a traction-truck supporting the rear end of said frame, a steering-truck supporting the forward end of said frame, a boiler mounted on said frame, steering mechanism mounted on said frame and connected with said steering-truck, driving mechanism mounted on said frame and arranged for connection with the traction mechanism at times and with a machine to be driven at times, an engine mounted on said frame, connections between said engine and the driving mechanism, a hoisting mechanism carried by said frame and arranged to be connected to the driving mechanism at times, a cable leading from said hoisting mechanism, guides for said cable, the steering mechanism, driving mechanism, engine, connections and hoisting mechanism being independent of the boiler.

5. In a traction-engine, a rigid frame, a traction-truck supporting the rear end of said frame, a steering-truck supporting the forward end of said frame, a boiler mounted on said frame, steering mechanism mounted on said frame and connected with said steering-truck, driving mechanism mounted on said frame and arranged for connection with the traction mechanism at times and with a machine to be driven at times, an engine mounted on said frame, connections between said engine and the driving mechanism, a hoisting mechanism carried by said frame and arranged to be connected to the driving mechanism at times, the rigid frame formed with an opening in its forward end, guides above and below said opening, and a cable leading from said hoisting mechanism through said opening and between said guides, the steering mechanism, driving mechanism, engine, connections and hoisting mechanism being independent of the boiler.

6. In a traction-engine, a rigid frame, trucks supporting said frame, a pillow-block on said frame, a boiler supported on said pillow-block and frame, engine-beds supported on said frame independent of the boiler, engines supported on said beds independent of the boiler, traction mechanism on said frame independent of the boiler, driving mechanism mounted on said frame independent of the boiler, and adapted to be connected to the traction mechanism at times and to a machine to be driven at times, connections between said engines and said driving mechanism, a hoisting mechanism carried by said frame independent of the boiler, detachable connections between said hoisting mechanism and the driving mechanism, a cable leading from said hoisting mechanism, and guides for said cable.

7. In a traction-engine, a rigid frame, traction-trucks and steering-trucks supporting said frame, an engine and driving mechanism on said frame, detachable connections between said driving mechanism and the traction-trucks, a hoisting-shaft transversely of said frame, detachable connections between said hoisting-shaft and the driving mechanism and a cable leading from and adapted to be wound on said hoisting-shaft.

8. In an engine a frame formed of channel-iron bent on opposite sides of its center and having its end portions extended in parallel lines, a steering-truck supporting the closed forward end portion of said frame, a traction-truck supporting the rear open end portion of said frame, an engine and driving mechanism mounted on said frame, detachable connections between said driving mechanism and the traction-truck, and a boiler mounted on said frame independent of the engine and driving mechanism.

9. In an engine, a supporting-frame formed with an aperture in its forward end, an engine and driving mechanism mounted on said frame, a hoisting-shaft mounted across said frame, detachable connections between said driving mechanism and hoisting-shaft, guide-rollers on said frame above and below the apertures therein, and a

cable leading from and adapted to be wound on said hoisting-shaft and extending through said aperture and between said guide-rollers.

10. In a traction-engine, a supporting-frame formed with an aperture in one end, guide-rollers opposite each other and extending into said aperture, a drum-shaft mounted transversely of said frame adjacent said aperture and parallel with said rollers, a cable on said shaft and extending through said aperture between said rollers, and means for driving said shaft, the said means comprising a pinion on said shaft, a gear-wheel meshing with said pinion, a pinion on the shaft of said gear-wheel, a gear-wheel meshing with said last-named pinion, and a pinion on the shaft of said last-named gear-wheel.

11. In a traction-engine, a rigid frame, trucks supporting said frame, a pillow-block on said frame, a boiler supported on said pillow-block and frame, engine-beds supported on said frame independent of the boiler, engines supported on said beds independent of the boiler, traction mechanism on said frame independent of the boiler, driving mechanism mounted on said frame independent of the boiler, and adapted to be connected to the traction mechanism at times and to a machine to be driven at times, connections between said engines and said driving mechanism, a hoisting mechanism carried by said frame independent of the boiler, detachable connections between said hoisting mechanism and the driving mechanism, a cable leading from said hoisting mechanism, guides for said cable, and a pinion on said shaft, a gear-wheel meshing with said pinion, a pinion on the shaft of said gear-wheel, a gear-wheel meshing with said last-named pinion, and a pinion on the shaft of said last-named gear-wheel.

12. In a traction-engine, a rigid frame, trucks supporting said frame, a pillow-block on said frame, a boiler supported on said pillow-block and frame, engine-beds supported on said frame independent of the boiler, engines supported on said beds independent of the boiler, traction mechanism on said frame independent of the boiler, driving mechanism mounted on said frame independent of the boiler, and adapted to be connected to the traction mechanism at times and to a machine to be driven at times, connections between said engines and said driving mechanism, a hoisting mechanism carried by said frame independent of the boiler, detachable connections between said hoisting mechanism and the driving mechanism, a cable leading from said hoisting mechanism, guides for said cable, and a pinion on said shaft, a gear-wheel meshing with said pinion, a pinion on the shaft of said gear-wheel, a gear-wheel meshing with said last-named pinion, and a pinion on the shaft of said last-named gear-wheel, the several openings located between the circumference of the barrel and the bore of the piece, and the ingress to the rear of the piece.

Claim.—1. In combination, a fence-post provided with a plurality of notches at intervals in its length forming seats for wires, over a single line of the message, means for causing successive lines

cable leading from and adapted to be wound on said hoisting-shaft and extending through said aperture and between said guide-rollers.

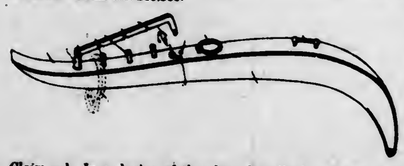
10. In a traction-engine, a rigid frame, trucks supporting said frame, a pillow-block on said frame, a boiler supported on said pillow-block and frame, engine-beds supported on said frame independent of the boiler, engines supported on said beds independent of said boiler, driving mechanism actuated by said engines, traction mechanism arranged for attachment to said driving mechanism at times, and steering mechanism arranged for manual operation of the forward truck.

812,138. WASHING-MACHINE. CHARLES L. KELLY, Grant, Ky. Filed June 13, 1905. Serial No. 265,020.

Claim.—1. In a washing-machine, a tub, a pair of rock-shafts journaled therein, links carried by the rock-shafts, a frame pivoted to the normally upper ends of the links and provided with a keeper, a rubbing member pivoted to the normally lower ends of the links, a second rubbing member pivoted at one end of the frame and adapted to swing upward, and a locking member carried by the second rubbing member for engagement with the keeper to lock said member in normal position in the frame.

2. In a washing-machine, a tub, a pair of rock-shafts journaled therein, links fixed upon the shafts to project normally above and below the same, closures extended between the links at opposite sides of the shaft, a frame pivoted to the upper ends of the links and provided with a keeper, a rubbing member journaled to the lower ends of the links, a second rubbing member pivoted in the frame and adapted to swing upward therefrom, a locking member carried by the second rubbing member for engagement with the keeper to lock the member in normally closed position, and means for operating the shafts to reciprocate the rubbing members relatively.

812,139. HAME. HENRY N. KEMPTON, Terry, Mont. Filed May 13, 1905. Serial No. 260,308.



Claim.—1. In a device of the class described, a hame, a plurality of relatively-spaced outwardly-projecting arms carried thereby, said arms being provided at their outer ends with seats or recesses, a pivoted keeper adapted to close over said arms and seat within said recesses, and means for locking the keeper in closed position.

2. In a device of the class described, a hame provided with a plurality of spaced members, a movable keeper adapted to close over said members and a pivoted locking member designed for engagement with the keeper to lock the latter against movement.

812,140. GUN-BARREL FOR PISTOLS, RIFLES, AND ORDNANCE. PERRY B. KNOX, Utica, N. Y. Filed June 14, 1901. Renewed July 25, 1905. Serial No. 267,944.

Claim.—1. A rifled barrel containing a series of perforations at the muzzle, adjacent to and encircling the bore, having the egress of the several openings located between the circumference of the barrel and the bore of the piece, and the ingress to the rear of the muzzle.

2. A rifled barrel containing a series of longitudinal gas-escape channels located between the circumference of the barrel and the periphery of the bore, having their openings at the muzzle, and intersecting the bore rearwardly thereof, permitting a portion of the gas-pressure to thereby escape past the bullet, in direction of and substantially parallel to the line of flight, prior to the exuding of the bullet, thus forming a preceding, encompassing, and separate current from the one immediately thereafter issuing from the bore.

3. A rifled barrel containing a series of perforations encircling the muzzle, entering the bore at an angle to the line of flight, with means which enter into said perforations by means of which one or more of said perforations can be diminished, adjusted or varied in capacity.

4. A rifle-barrel containing a series of perforations encircling the muzzle and entering the bore of the piece, in combination with one or more plugs inserted therein for regulating the escape of gas therefrom.

5. A gun-barrel containing a series of perforations or gas-escape openings encircling the muzzle, with one or more plugs inserted therein, for the purpose of reducing or regulating the maximum flow of gas therefrom.

6. A rifled barrel perforated at or near the muzzle with a series of holes encircling the same and radiating from the bore outward with means for partially closing said holes by the use of plugs or their equivalent entering said holes, essentially as shown and described.

7. A rifled barrel containing a series of perforations or gas-escape openings encircling the muzzle and entering the bore thereof, with means entering into any one or more of said perforations by which the circumferential area of gas-escape may be diminished, regulated or changed wholly or in part, essentially as described.

8. A rifle-barrel containing a series of perforations or gas-escape openings encircling the muzzle, and means by which the longitudinal area of gas-escape may be varied, regulated, or changed independently of the circumferential area, essentially as set forth.

9. A rifled barrel containing a series of perforations or gas-escape openings near the nozzle, with means consisting of perforated plugs inserted therein, by which the distance from the muzzle to the nearest full openings may be increased or diminished, and the area or volume of escape be thereby changed or regulated as desired.

10. A gun-barrel containing a series of gas-escape openings encircling the bore, fitted with plugs containing openings through which the propelling force may find exit prior to the bullet leaving the muzzle thereof.

11. A gun-barrel containing a multiple of longitudinal gas-escape channels, adjacent to and encircling the bore of the piece, having their exits between the circumference of the barrel and the periphery of the bore, intersecting the bore rearwardly of the muzzle, through which a portion of the gas-pressure may escape prior to the parting of the rear end of the bullet with the muzzle of the piece in direction of the line of flight: in combination with spirally-cut grooves or rifling within the bore of the piece.

12. A rifle-barrel containing a series of lateral gas-escape channels, one or more of which are estopped at the outer opening of same with plugs, coalescing with a series of longitudinal gas-escape channels located between the circumference of the bore and the circumference of the barrel, permitting the gas to escape approximately parallel to the line of flight separately from the blast issuing from the bore.

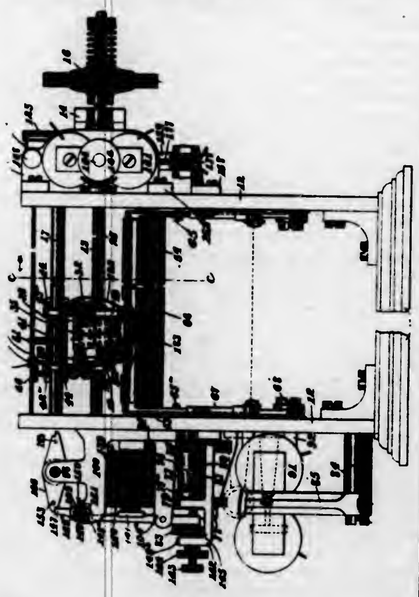
812,141. FENCE-POST. JAMES W. KIDD, Okmulgee, Okla. Filed June 20, 1905. Serial No. 266,139.

Claim.—1. In combination, a fence-post provided with a plurality of notches at intervals in its length forming seats for fence-wires, fence-wires received in the notches, and a tie member of U form with one side thereof disposed on one side of the post to engage the fence-wires, the other side of the tie member being disposed on the opposite side of the post and coöperating to prevent displacement of the fence-wires from the notches and displacement of the tie member from the post.

2. In combination, a fence-post having a plurality of seats to receive the line-wires, a tie member to engage the line-wires and prevent displacement thereof, and a band about the post adapted to prevent displacement of the tie member.

3. In combination, a fence-post provided with relatively notched portions forming seats, a U-shaped tie member adapted to embrace opposite sides of the fence-post, and a band about said post provided with a loop to engage a side of the tie member.

812,142. FACSIMILE-TELEGRAPH. EDUARD E. KLEINSCHMIDT, New York, N. Y., assignor to Frederick Kleinschmidt, New York, N. Y. Filed Jan. 18, 1901. Serial No. 43,754.



Claim.—1. A facsimile-telegraph comprising means for holding a message-sheet, a plurality of styluses arranged to travel in a straight line over a single individual and legibly separate line of the message, means for causing successive lines of the message to be intermittently presented to and to be traversed by the said styluses, and means for connecting the said styluses to a single line-wire.

2. A facsimile-telegraph comprising means for holding a message-sheet, a plurality of styluses, means for causing the styluses to travel over a portion of a line of the message in a direction at right angles to the direction of the line, and means for causing the styluses to travel over successive portions of the line.

3. A facsimile-telegraph, comprising means for holding a message-sheet, a plurality of styluses, means for causing the styluses to travel over a specific portion of a line of a message, and means for shifting the styluses at intermittent intervals a distance approximately equal to the length of the specific portion traversed.

4. A facsimile-telegraph comprising means for holding a message-sheet, a plurality of styluses, means for causing the styluses to travel over a portion of a line of the message in a direction at an angle to the direction of the line and a spiral course over the said portion of the line, and means for causing the styluses to travel over successive portions of the line.

A facsimile-telegraph, comprising means for holding a message-sheet, a plurality of styluses arranged to travel transversely over a single line of the message, means for causing successive lines of the message to be traversed by the said styluses, and means for connecting the said styluses to a single line-wire.

6. A facsimile-telegraph, comprising means for holding a message-sheet, a plurality of styluses arranged to travel transversely over a single line of the message, means for causing successive lines of the message to be traversed by the said styluses, and means for causing the styluses to travel in opposite directions over the alternate lines.

7. A facsimile-telegraph, comprising means for holding a message-sheet, a plurality of styluses arranged to travel over a specific legibly-separate area or self-distinguishable portion of the message longitudinally of the message-sheet and at an angle to the transverse direction of the message across the message-blank, and means for causing the styluses to move transversely of the message-sheet to cover successive portions of the message.

8. A facsimile-telegraph, comprising means for holding a message-sheet, a plurality of styluses arranged to travel over a specific legibly-separate area or self-distinguishable portion of the message and at an angle to the transverse direction of the message across the message-blank, and means for moving the styluses to successive portions of the message and for causing the styluses to travel over such portions at separate intervals.

9. A facsimile-telegraph, comprising means for holding a message-sheet a plurality of styluses arranged to travel in a path longitudinally of the message-sheet over a certain specific legibly-separate area or self-distinguishable portion and at an angle to the transverse direction of the message across the message-blank, means for causing the said styluses to travel over similar portions of the message transversely thereof, and means for presenting successive portions of the message to the styluses.

10. A facsimile-telegraph, comprising means for holding a message-sheet, a plurality of styluses arranged to travel transversely over a single line of the message; means for causing the said styluses to transmit a specific legibly-separate area or self-distinguishable portion of the said line, means for stopping the said styluses and shifting them to successive portions of the said line and means for presenting successive lines of the message to said styluses.

11. A facsimile-telegraph, comprising means for holding a message-sheet, a plurality of styluses arranged to travel longitudinally of the message-sheet over a certain specific legibly-separate area or self-distinguishable portion of the message to transmit the same, means for stopping the said styluses and shifting them transversely to the next following successive portion of the same line, and means for advancing the message-sheet successive spaces of one line each to present successive lines of the message to the styluses.

12. A facsimile-telegraph, comprising means for holding a message-sheet, a plurality of styluses arranged in circular series; means for causing said styluses to travel in a vertical plane over the message-sheet to successively contact with fragmentary particles of the message, means for causing the styluses to travel in a spiral course over a line of the message and means for moving the styluses to successive portions of the message.

13. A facsimile-telegraph comprising means for holding a message-sheet, a plurality of styluses arranged in a circular series; means for causing said styluses to travel in a vertical plane over the message-sheet at an angle to the direction of the line to successively contact with fragmentary particles of the message and means for moving the styluses to successive portions of the message.

14. A facsimile-telegraph comprising means for holding a message-sheet, a plurality of styluses arranged in a circular series; means for causing said styluses to travel in a vertical plane over the message-sheet at an angle to the direction of the line to successively contact with fragmentary particles of the message, means for causing the styluses to travel in a spiral course over a line of the message and means for moving the styluses to successive portions of the message.

15. A facsimile-telegraph, comprising means for holding a message-sheet, a plurality of styluses arranged in circular series; means for causing the said styluses to travel in a vertical plane longitudinally of the message-sheet to transmit a certain specific legibly-separate area or self-distinguishable portion of the message, means for causing the styluses to travel transversely over a single line of the message to transmit successive portions of the same, and means for causing successive lines of the message to be traversed by said styluses.

16. A facsimile-telegraph, comprising means for holding a message-sheet, a plurality of styluses arranged in circular series; means for causing said styluses to travel in a vertical plane whereby successively to contact with the message-sheet, means for moving said styluses over a single line of the message, means for causing succes-

---

sive lines of the message to be traversed by said styluses, and means for causing the styluses to travel in opposite directions over the al-

27. In a facsimile-telegraph, comprising means for holding a message-sheet, a rotary stylus-carrier provided with

---

39. In a facsimile-telegraph, a rotary stylus-carrier comprising a block of insulating material, a metallic casing surrounding the

intermittently actuates the turning devices, spring-operated means for throwing the said turning devices out of connection with the feed-

sive lines of the message to be traversed by said styluses, and means for causing the styluses to travel in opposite directions over the alternate lines.

17. A facsimile-telegraph, comprising means for holding a message-sheet, and a rotary stylus-carrier, a plurality of styluses mounted upon the said stylus-carrier in a substantially spiral series; means for causing said stylus-carrier to rotate in a vertical plane relatively to the message-sheet whereby the styluses will successively contact therewith at diffent portions of the sheet to transmit a certain specific legibly-separate area or self-distinguishable portion of the message, means for shifting the said stylus-carrier whereby the styluses will rotate over successive portions of the same line of the message, means for presenting successive lines of the message to the said styluses.

18. A facsimile-telegraph, comprising means for holding a message-sheet, and a rotary stylus-carrier, a plurality of styluses mounted upon the said stylus-carrier; means for causing said stylus-carrier to rotate in a vertical plane respectively to the message-sheet whereby the styluses will successively contact therewith at different portions of the sheet to transmit a certain specific legibly-separate area or self-distinguishable portion of the message; means for shifting the said stylus-carrier whereby the styluses will rotate over successive portions of the same line of the message and means for presenting successive lines of the message to the said styluses.

19. In a facsimile-telegraph comprising means for holding a message-sheet, and a rotary stylus-carrier, a plurality of styluses mounted upon the said stylus-carrier in a substantially spiral series; means for causing said stylus-carrier to rotate in a vertical plane respectively to the message-sheet whereby the styluses will successively contact therewith at different portions of the sheet to transmit a portion of the message, means for operating the said stylus-carrier whereby the styluses will rotate over successive portions of the same line of the message; and means for presenting successive lines of the message to the said styluses.

20. A facsimile-telegraph, comprising means for holding a message-sheet, a rotary stylus-carrier, means for rotating the same in a vertical plane relatively to the message-sheet, a plurality of styluses arranged in a substantially spiral series around the said carrier, means for shifting the said carrier to successive portions of the message, and means for stopping and starting said carrier when thus shifting the same.

21. A facsimile-telegraph comprising a message-sheet, a rotary stylus-carrier; means for rotating the same in a vertical plane relatively to the message-sheet; and a plurality of styluses arranged in a substantially spiral series around the said carrier.

22. A facsimile-telegraph comprising means for holding a message-sheet, a rotary stylus-carrier provided with a plurality of styluses traveling in a vertical plane relatively to the message-sheet, means for shifting the said stylus-carrier transversely of the message-sheet to transmit successive portions of the same line, and means for advancing the message-sheet the successive spaces of one line.

23. A facsimile-telegraph, comprising means for holding a message-sheet, a rotary stylus-carrier provided with a plurality of styluses traveling in a vertical plane relatively to the message-sheet, means for operating the said stylus-carrier transversely in a specific direction of the message-sheet to transmit successive portions of the same line, and means for advancing the message-sheet the successive spaces of one line.

24. A facsimile-telegraph, comprising means for holding a message-sheet, a rotary stylus-carrier provided with a plurality of styluses traveling in a vertical plane relatively to the message-sheet, means for shifting the said stylus-carrier transversely of the message-sheet to transmit successive portions of the same line, means for causing the stylus-carrier to travel in a reverse direction over each alternate line, and means for actuating the paper-advancing means and the stylus-carrier-reversing means simultaneously.

25. A facsimile-telegraph, comprising means for holding a message-sheet, a rotary stylus-carrier, means for causing said carrier to rotate in a vertical plane relatively to the message-sheet, a plurality of electrically-separated circular series of styluses upon the said stylus-carrier, whereby a plurality of styluses will be simultaneously in contact with the message-sheet; and means for connecting the said plurality of series of styluses to a single line-wire.

26. A facsimile-telegraph comprising means for holding a message-sheet, a rotary stylus-carrier provided with styluses extending around the same and traveling in a vertical plane with respect to the message-sheet, means for rotating said stylus-carrier in a constant plane spirally of the transverse course or direction of the message, means for shifting the said stylus-carrier to successive portions of the message, and means for changing the direction of the shifting means.

27. In a facsimile-telegraph, comprising means for holding a message-sheet, a rotary stylus-carrier provided with styluses extending around the same and traveling in a vertical plane with respect to the message-sheet, means for rotating said stylus-carrier in a constant plane spirally of the transverse course or direction of the message, and means for operating the said stylus-carrier to traverse successive portions of the message.

28. A facsimile-telegraph, comprising means for holding a message-sheet. a rotary stylus-carrier provided with a plurality of styluses arranged around the same and traveling in a vertical plane with respect to the message-sheet, means for rotating the stylus-carrier, means for stopping and starting the stylus-carrier at intervals, and means for shifting the stylus-carrier to successive portions of the message when the carrier is stopped.

29. A facsimile-telegraph, comprising means for holding a message-sheet, a rotary stylus-carrier provided with styluses extending around the same and traveling in a vertical plane relatively to the message-sheet, means for rotating the said stylus-carrier; means for stopping the carrier at intervals, means actuated by the stopping means for starting and stopping the carrier, and means for shifting the carrier to successive portions of the message.

30. A facsimile-telegraph, comprising means for holding a message-sheet, a rotary stylus-carrier provided with styluses extending around the same and traveling in a vertical plane relatively to the message-sheet, means for rotating the said stylus-carrier in constant plane, means for stopping and starting the same at each revolution thereof; means for shifting the said carrier to successive portions of the message after each revolution; means for changing the direction of the shifting means and means for advancing the message-sheet the successive space of one line at each change of direction of the shifting means of the carrier.

31. In a facsimile-telegraph, a rotary stylus-carrier adapted to be operated in a vertical plane, two series of styluses extending around said stylus-carrier in a substantially spiral arrangement, each series being electrically separated from the other, electrical connections from each of the series of styluses to a single line-wire, and means for separating the impulses of said styluses.

32. In a facsimile-telegraph, a rotary stylus-carrier adapted to be operated in a vertical plane, two series of styluses extending around said stylus-carrier, each series being electrically separated from the other, electrical connections from each of the series of styluses to a single line-wire, and means for separating the impulses of said styluses.

33. In a facsimile-telegraph, a rotary transmitting stylus-carrier comprising two insulated sections, and two series of transmitting-styluses mounted respectively upon said sections, and means for sending separate impulses from the styluses of each series.

34. In a facsimile-telegraph, a rotary stylus-carrier comprising a block of insulated material, metallic sections secured upon said block and mutually disconnected, and two series of styluses mounted in a substantially spiral arrangement respectively upon said sections, whereby they will range parallel one with the other.

35. In a facsimile-telegraph, a rotary stylus-carrier comprising a block of insulated material, a metallic casing surrounding the same and divided into electrically-separated sections, and two series of styluses connected respectively with the said sections and projecting radially of the stylus-carrier, the inner ends of the said styluses being inserted in the insulated block.

36. In a facsimile-telegraph, the combination with a main rotary shaft and a worm-shaft, of the revoluble stylus-carrier having its frame mounted upon the said worm-shaft and its body portion slidably mounted upon the main shaft of a tube extending across the frame, a pair of nuts mounted in the ends of the said tube and engaging the worm-shaft and means for adjusting the said nuts and for securing the tube to the frame.

37. In a facsimile-telegraph, the combination with a rotary shaft, of a stylus-carrier mounted thereon and consisting of an insulating-block, spirally cut out upon its periphery, a sectional metallic casing secured upon the said block, styluses mounted in the said sectional casing, and in the said block and projecting radially, caps or collars mounted upon each end of the insulating-block and connected thereto and to the sectional casing, and electrically separate from the rotary shaft, and brushes at either side of the carrier bearing respectively upon the end caps or collars.

38. In a facsimile-telegraph, a rotary stylus-carrier comprising a block of insulating material, a metallic casing surrounding the same and divided into electrically-separate sections formed with a spiral slot between them, plates secured to the said casing at either side of the slot, and two series of styluses mounted in the said plates, and projecting radially of the stylus-carrier.

39. In a facsimile-telegraph, a rotary stylus-carrier comprising a block of insulating material, a metallic casing surrounding the same and divided into electrically-separate sections formed with a spiral slot between them, plates secured to the said casing at either side of the slot, and two series of styluses mounted in the said plates, and projecting radially of the stylus-carrier; the inner ends of the said styluses being yieldingly and slidably mounted in the insulating-block.

40. In a facsimile-telegraph, the combination with a main rotary shaft and a parallel worm-shaft, of a stylus-carrier, comprising a frame mounted upon the worm-shaft and provided with adjustable nuts and working upon the said worm-shaft; means for adjusting the position of the stylus-carrier upon the worm, and a rotary body portion mounted upon the rotary shaft and slidable thereon, the said rotary body portion being provided with circular series of styluses mounted therein.

41. In a facsimile-telegraph, the combination with a rotary stylus-carrier and means for actuating the same, of a message-paper-feed roller mounted in vertical alinement with the stylus-carrier, spring-actuated pressure-rollers bearing against either side of the feed-roller, means for moving the feed-roller in a vertical path away from the stylus-carrier, means for limiting the movement of the pressure-rollers when the feed-roller is withdrawn, and means for throwing the feed-roller back to position and sustaining it.

42. In a facsimile-telegraph, the combination with a rotary stylus-carrier and means for actuating the same, of a message-paper-feed roller mounted in relation to the said stylus-carrier, pressure-rollers bearing against either side of the same, adjustable cams above the feed-roller to limit its upward movement, and operating-cams below the said roller for raising and lowering the same.

43. In a facsimile-telegraph, the combination with a rotary stylus-carrier and means for actuating the same, of a message-paper-feed roller mounted in relation to the said stylus-carrier, and intermittent means for turning the said roller to advance the message-paper the distance of one line after the stylus-carrier has traversed one line of the message.

44. In a facsimile-telegraph, the combination with a rotary stylus-carrier and means for actuating the same, of a message-paper-feed roller, and means actuated by the stylus-carrier to the end of each line for turning the feed-roller to advance the message-sheet the distance of one line after the stylus-carrier has traversed one line of the message.

45. In a facsimile-telegraph, the combination with a rotary stylus-carrier and means for actuating the same, of a message-paper-feed roller, and electrically-actuated means actuated by the stylus-carrier at the end of each line for turning the feed-roller to advance the message-sheet the distance of one line after the stylus-carrier has traversed one line of the message.

46. In a facsimile-telegraph, the combination with a rotary stylus-carrier and means for actuating the same, of a message-paper-feed roller, and electrically-actuated means actuated by the stylus-carrier for turning the feed-roller to advance the message-sheet the distance of one line after the stylus-carrier has traversed one line of the message.

47. In a facsimile-telegraph the combination with a rotary stylus-carrier and means for actuating the same of a message-paper-feed roller, means for moving the stylus-carrier longitudinally of the said roller, and means for turning the said roller to advance the message-sheet the distance of one line, said means being actuated by the stylus-carrier at the end of its travel over each line of the message.

48. In a facsimile-telegraph, the combination with a rotary stylus-carrier and means for actuating the same, of a message-paper-feed roller mounted in relation thereto, means for raising and lowering the said feed-roller, means for intermittently turning the same; means for throwing the turning devices out of connection therewith to prevent rotation thereof and permit of its raising and lowering.

49. In a facsimile-telegraph, the combination with a rotary stylus-carrier, and means for actuating the same, of a message-paper-feed roller mounted in relation to said stylus-carrier, means for raising and lowering the same, a gear carried by one end of the roller, a gear in connection therewith to rotate the same; means actuated by the stylus-carrier for operating the latter gear at the end of each line of the message, and means for throwing the said gear out of engagement with the gear on the feed-roller.

50. In a facsimile-telegraph, the combination with a rotary stylus-carrier, and means for actuating the same, of a message-paper-feed roller, mounted beneath the stylus-carrier, pressure-rollers at either side thereof, means for raising and lowering the said feed-roller; means for turning the same, means whereby the stylus-carrier intermittently actuates the turning devices, spring-operated means for throwing the said turning devices out of connection with the feed-roller, and means for holding the said devices in connection therewith against the spring.

51. In a facsimile-telegraph, the combination with a rotary stylus-carrier, and means for actuating the same, of a message-paper-feed roller mounted beneath the same, pressure-rollers at either side thereof, means for raising and lowering the said feed-roller, a gear carried by the said feed-rolle , a slidable gear adapted to engage therewith to turn the roller, a hollow shaft on which the latter gear is slidably mounted, a spring tending to slide the said gear normally out of engagement with the gear of the feed-roller, and a screw adapted to press the slide of the said gear into engagement against the spring.

52. In a facsimile-telegraph, the combination with a rotary stylus-carrier, and means for actuating the same, of a message-paper-feed roller mounted beneath the said stylus-carrier and adapted to raise and lower the same adjustable cams above the said roller for limiting its upward movement, operating-cams below the said roller for raising and lowering the same and to maintain it in the raised position, spring-actuated pressure-rollers at either side of the paper-feed roller, means for limiting the inward movement of the said pressure-rollers when the feed-roller is lowered, a gear upon the end of the feed-roller, a gear mounted in engagement with the same, a hollow slotted shaft on which the said gear is slidably mounted, the said gear being provided with a pin which projects through the slot of the shaft a spring within the shaft tending to throw the gear normally out of engagement with the gear of the feed-roller, and a screw mounted in the hollow shaft and bearing against the pin to slide the gear into engagement against the spring.

53. In a facsimile-telegraph, the combination with a rotary stylus-carrier, and a shaft for actuating the same, of means in connection with the said shaft for shifting the stylus-carrier longitudinally thereof intermittently.

54. In a facsimile-telegraph, the combination with a rotary shaft, and a stylus-carrier mounted thereon, to rotate therewith and longitudinally movable thereupon of means in connection with the said shaft for stopping the same intermittently, and means upon and in connection with the said shaft for shifting the said stylus-carrier longitudinally thereof intermittently.

55. In a facsimile-telegraph, the combination with a rotary shaft, and a stylus-carrier mounted thereon to rotate therewith and longitudinally movable thereupon of means upon and in connection with the said shaft for stopping the same intermittently; means for shifting the stylus-carrier longitudinally thereof intermittently, and means actuated by the stop devices for releasing the shaft.

56. In a facsimile-telegraph the combination with a rotary shaft and a stylus-carrier mounted thereon to rotate therewith and longitudinally movable thereupon, of means upon and in connection with the said shaft for stopping the same intermittently; means upon and in connection with the said shaft for shifting the said stylus-carrier longitudinally thereof intermittently, means for reversing the direction of movement of the stylus-carrier, and means carried by the stylus-carrier for actuating the reversing means at the end of each line of travel of the said carrier.

57. In a facsimile-telegraph, the combination with a rotary shaft, and a stylus-carrier mounted thereon to rotate therewith and longitudinally movable thereupon, of means upon and in connection with the said shaft for stopping the same intermittently, means upon and in connection with the said shaft for shifting the stylus-carrier longitudinally thereof intermittently; means for reversing the direction of movement of the stylus-carrier; means carried by the stylus-carrier for actuating the reversing means at the end of each line of travel of the said carrier, means for supporting a message-sheet in relation to the stylus-carrier, means for advancing the message-sheet successive distances of one line and means whereby the said message-sheet-advancing means will be actuated at the end of each line of travel of the stylus-carrier.

58. In a facsimile-telegraph, the combination with a rotary shaft, and a stylus-carrier mounted thereon to rotate therewith and longitudinally movable thereupon, of stop devices upon the said shaft, a magnet mounted adjacent thereto, an armature-lever mounted in connection with the magnet and comprising means for engaging the stop device of the shaft, and means for energizing the said magnet to attract the armature-lever and release the shaft.

59. In a facsimile-telegraph, the combination with a rotary shaft, and a stylus-carrier mounted thereon to rotate therewith and longitudinally movable thereupon, of stop devices upon the said shaft; a magnet mounted adjacent thereto, an armature-lever mount-

ed in connection with the magnet and comprising means for engaging the stop device of the shaft, and means upon and in connection with the armature-lever whereby the contact of the stop device of the shaft therewith will initiate the energizing on the magnet to attract the said armature-lever and release the shaft.

60. In a facsimile-telegraph, the combination with a rotary shaft, and a stylus-carrier mounted thereon to rotate therewith and longitudinally movable thereupon, of stop devices upon the said shaft, a magnet mounted adjacent thereto, an armature-lever mounted in connection with the magnet and comprising means for engaging the stop device of the shaft, a sliding contact device mounted upon the armature-lever and adapted to be moved by the stop device of the shaft; a second contact device upon the said lever which the sliding contact normally engages, a circuit including the said contacts and adapted to energize the magnet when the contacts are disengaged, whereby the movement of the sliding contact will initiate the energizing of the said magnet to attract the armature-lever and release the shaft.

61. In a facsimile-telegraph, the combination with a rotary shaft and a stylus-carrier mounted thereon, of a stop device carried by the said shaft, a magnet mounted adjacent thereto, an armature-lever mounted in relation to the said magnet and provided with a shoulder, means for normally retracting the armature-lever to bring the shoulder into the path of movement of the stop device of the shaft, normally engaging contacts upon the said armature-lever adapted to be disconnected by the engagement of the stop device with the shoulder thereof, a circuit including the said contacts and a source of electrical energy which is short-circuited when the contacts engage, and means whereby when the short circuit is broken the current thereof will energize the magnet to attract the armature and withdraw its shoulder from the stop device.

62. In a facsimile-telegraph the combination with a main rotary shaft and a stylus-carrier mounted thereon and longitudinally movable thereupon of a shifting-shaft connected with the stylus-carrier and adapted to move the same longitudinally of its shaft, rotary means for actuating the shifting-shaft and means for permitting the same intermittently to actuate the shifting-shaft.

63. In a facsimile-telegraph, the combination with a main rotary shaft and a stylus-carrier mounted thereon and longitudinally movable thereupon, of a shifting-shaft connected with the stylus-carrier and adapted to move the same longitudinally of its shaft, rotary means for actuating the shifting-shaft, and means actuated by the stylus-shaft for permitting the same intermittently to actuate the shifting-shaft.

64. In a facsimile-telegraph, the combination with a main rotary shaft and a stylus-carrier mounted thereon and longitudinally movable thereupon, of a shifting-shaft connected with the stylus-carrier and adapted to move the same longitudinally of its shaft, means in connection therewith for communicating rotary motion to the shifting-shaft intermittently, electromagnetic devices for operating the intermittent devices and means for causing the said electromagnetic devices to act at each specific number of revolutions of the stylus-shaft.

65. In a facsimile-telegraph, the combination with a main rotary shaft and a stylus-carrier mounted thereon and longitudinally movable thereupon, of a shifting-shaft for moving the stylus-carrier upon its shaft, a sectional rotary shaft geared to the said shifting-shaft, and means for connecting and disconnecting the sections of the shaft to cause the same intermittently to actuate the shifting-shaft.

66. In a facsimile-telegraph, the combination with a main rotary shaft and a stylus-carrier mounted thereon and longitudinally movable thereupon, of a shifting-shaft for moving the said stylus-carrier upon its shaft, a sectional rotary shaft geared to the said shifting-shaft, a friction-clutch connecting the said sections, and stop devices upon one of the sections, stop devices mounted adjacent thereto to engage the same to stop the said sectional shaft, and means for intermittently releasing the said section.

67. In a facsimile-telegraph, the combination with a main rotary shaft and a stylus-carrier mounted thereon and longitudinally movable thereupon, of a shifting-shaft connected with the stylus-carrier and adapted to move the same longitudinally of its shaft, a rotary shaft geared thereto, and means for reversing the gear connections of the rotary shaft and the shifting-shaft whereby the stylus-carrier may be moved in opposite directions.

68. In a facsimile-telegraph, the combination with a main rotary shaft and a stylus-carrier mounted thereon and longitudinally movable thereupon of a shifting-shaft connected with the stylus-carrier and adapted to move the same upon its shaft, a sectional rotary shaft geared to the said shifting-shaft, a friction-clutch connecting the sections stop devices upon one of the said sections, stop devices mounted adjacent thereto, a magnet mounted in relation thereto, an armature-lever adapted when attracted by the said magnet to disengage the stop devices and permit partial revolution of the rotary shaft-section, and means operated by the stylus-shaft for energizing the said magnet.

69. In a facsimile-telegraph, the combination with a main rotary shaft and a stylus-carrier mounted thereon and longitudinally movable thereupon, of a shifting-shaft connected with the stylus-carrier and adapted to move the same longitudinally of its shaft, and means governed by the stylus-shaft for actuating the said connecting means intermittently at a specific number of revolutions of the said shaft.

70. In a facsimile-telegraph, the combination with a main rotary shaft and a stylus-carrier mounted thereon and longitudinally movable thereupon, of the shifting-shaft connected to the said stylus-carrier to move the same upon its shaft, a sectional rotary shaft geared in connection with the said shifting-shaft, a friction-clutch connecting the sections, stop devices upon one of the said sections, a pawl adapted to engage the same, a magnet mounted adjacent thereto, an armature-lever adapted when attracted to move the pawl and release the stop devices to permit partial revolution of the said shaft-section; a circuit including the said magnets, brushes mounted adjacent to the stylus-shaft, and means upon the stylus-shaft for connecting the said brushes at each specific number of revolutions thereof whereby to energize the magnets.

71. In a facsimile-telegraph, the combination with a main rotary shaft and a stylus-carrier mounted thereon and longitudinally movable thereupon, of a shifting-shaft connected to the said stylus-carrier to move the same upon its shaft, a sectional rotary shaft geared in connection with the said shifting-shaft a friction-clutch connecting the sections, stop devices upon one of the said sections, a pawl adapted to engage the same, a magnet mounted adjacent thereto, an armature-lever adapted when attracted to move the pawl and release the stop devices to permit partial revolution of the said shaft-section, a circuit including the said magnet, brushes mounted adjacent to the stylus-shaft means upon the stylus-shaft for connecting the said brushes at each specific number of revolutions thereof whereby to energize the magnet, means for reversing the gear connections of the rotary shaft and the shifting-shaft, an electromagnetic device for actuating the said reversing means and devices operated by the stylus-carrier for energizing the said electromagnetic devices.

72. In a facsimile-telegraph, the combination with a rotary stylus-carrier, of a message-paper-feed roller and a shaft with which it is adapted to turn, insulated heads in the said roller connecting the same with the shaft, an adjusting-nut mounted upon the shaft to tighten the roller thereon, and gear connections for turning the said roller which are adapted to be disconnected to permit adjustment thereof.

73. In a facsimile-telegraph, the combination with a rotary shaft and a stylus-carrier mounted thereon and longitudinally movable thereupon, of a worm-shaft ranging parallel with the stylus-shaft and connected with the stylus-carrier to move the same longitudinally, gears carried by the worm-shaft, rotary means for actuating the said gears, clutch devices for alternately connecting the gears to the worm-shaft; and electromagnetic means for actuating the said clutch devices.

74. In a facsimile-telegraph, the combination with a shaft and a stylus-carrier mounted thereon and longitudinally movable thereupon, of a shifting-shaft connected with the stylus-carrier to move the same upon its shaft; devices for reversing the action of the shifting-shaft, said devices being comprised in an electric circuit, and means for changing the polarity of the said circuit.

75. In a facsimile-telegraph, the combination with a shaft and a stylus-carrier mounted thereon and longitudinally movable thereupon, of a shifting-shaft connected with the stylus-carrier to move the same upon its shaft; devices for reversing the action of the shifting-shaft, said devices being comprised in a circuit, and means actuated by the stylus-carrier for changing the polarity of the circuit at the end of each line of travel of the stylus-carrier.

76. In a facsimile-telegraph, the combination with a rotary shaft and a stylus-carrier mounted thereon to rotate therewith and longitudinally movable thereupon, of means upon and in connection with the said shaft for stopping the same intermittently, means upon and in connection with the said shaft for shifting the said stylus-carrier longitudinally thereof intermittently, means comprised in an electric circuit for reversing the direction of movement of the stylus-carrier, and means actuated by the stylus-carrier for changing the polarity of the circuit.

77. In a facsimile-telegraph, the combination with a rotary

shaft and a stylus-carrier mounted thereon to rotate therewith and longitudinally movable thereupon, of means upon and in connection with the said shaft for stopping the same intermittently, means upon and in connection with the said shaft for shifting the said stylus-carrier longitudinally thereof intermittently; means comprised in an electric circuit for reversing the direction of movement of the stylus-carrier, a current-changer, a rod for actuating the current-changer, and means whereby the movement of the stylus-carrier actuates said rod.

78. In a facsimile-telegraph the combination with a rotary shaft and a stylus-carrier mounted thereon to rotate therewith and longitudinally movable thereupon, of means upon and in connection with the said shaft for stopping the same intermittently, means upon and in connection with the said shaft for shifting the said stylus-carrier longitudinally thereof intermittently, and means for reversing the direction of movement of the stylus-carrier, said means including magnets comprised in an electric circuit, an armature-lever connected with one of the magnets and means for changing the polarity of the armature-lever.

79. In a facsimile-telegraph the combination with a rotary shaft and a stylus-carrier mounted thereon to rotate therewith and longitudinally movable thereupon, of means upon and in connection with the said shaft for stopping the same intermittently, means upon and in connection with the said shaft for shifting the said stylus-carrier longitudinally thereof intermittently, means for reversing the direction of movement of the stylus-carrier and means including magnets comprised in an electric circuit, an armature-lever connected with one of the magnets and means for changing the polarity of the circuit, a current-changer included in the circuit and adapted to change the polarity of the current to the armature-lever and means controlled by the stylus-carrier for actuating the current-changer.

80. In a facsimile-telegraph the combination with a main rotary shaft and a stylus-carrier mounted thereon and longitudinally movable thereupon, of a shifting-shaft connected with the stylus-carrier and adapted to move the same longitudinally of its shaft, means controlled by the stylus-shaft for actuating the shifting-shaft intermittently, devices upon and in connection with the shifting-shaft for reversing the same, magnets comprised in an electric circuit, an armature connected to one of the magnets and to the shaft-reversing means, a current-changer included in the circuit, and means controlled by the stylus-carrier for actuating the current-changer to change the polarity of the armature-lever.

81. In a facsimile-telegraph, the combination with a main rotary shaft and a stylus-carrier mounted thereon and longitudinally movable thereupon, of a shifting-shaft connected with the stylus-carrier and adapted to move the same longitudinally of its shaft, means controlled by the stylus-shaft for actuating the shifting-shaft intermittently, devices upon and in connection with the shifting-shaft for reversing the same, magnets comprised in an electric circuit, an armature-lever connected to one of the magnets and to the shaft-reversing means, a current-changer included in the said circuit and comprising adjustable contacts, and contact devices mounted upon the same, a rod connected with the said contact devices, and means controlled by the stylus-carrier for shifting the said rod whereby the current-changer will change the polarity of the armature-lever.

82. In a facsimile-telegraph, the combination with a rotary shaft and a stylus-carrier mounted thereon to rotate therewith and longitudinally movable thereupon, of means upon and in connection with the said shaft for stopping the same intermittently; means upon and in connection with the said shaft for shifting the said stylus-carrier longitudinally thereof intermittently; means for reversing the direction of movement of the stylus-carrier, said means being comprised in an electric circuit and including a current-changer; a rod mounted adjacent to the stylus-carrier; a friction-sleeve upon the said rod, and connections from the stylus-carrier to the said friction-sleeve.

83. In a facsimile-telegraph, the combination with a main rotary shaft and a stylus-carrier mounted thereon and longitudinally movable thereupon, of a shifting-shaft connected with the stylus-carrier and adapted to move the same longitudinally of its shaft, means actuated by the stylus-shaft for causing the intermittent devices to act; devices upon and in connection with the shifting-shaft for reversing the same; magnets comprised in an electric circuit; an armature-lever connected to one of the magnets and to the shaft-reversing means; a current-changer included in the circuit devices and adapted to bring them in connection with the adjustable contacts; means bearing upon the said contact devices for governing the action thereof; a friction-sleeve mounted upon the said rod; and an arm upon the stylus-carrier connected with the said friction-sleeve.

84. In a facsimile-telegraph, the combination with a stylus-carrier and means for actuating the same, of a message-paper-feed roller; means comprised in an electric circuit for turning the said feed-roller specific distances, and means controlled by the stylus-carrier for closing the said circuit to operate the turning means.

85. In a facsimile-telegraph, the combination with a stylus-carrier and means for actuating the same, of a message-paper-feed roller, means comprised in an electric circuit for turning the said feed-roller specific distances, and means controlled by the stylus-carrier for closing the said circuit at the end of each line of travel of the stylus-carrier.

86. In a facsimile-telegraph, the combination with a stylus-carrier and means for actuating the same, of a message-paper-feed roller, means comprised in an electric circuit for turning the same specific distances, and means connected with the stylus-carrier and adapted to close the said circuit by contacting with markings upon the message-paper.

87. In a facsimile-telegraph, the combination with a stylus-carrier and means for actuating the same, of a message-paper-feed roller, means comprised in an electric circuit for turning the same specific distances, a brush connected with the stylus-carrier and adapted to close said circuit by contacting with markings upon the message-paper, and a relay limiting the closing of the said contacting means, whereby the circuit will be closed only by contact thereof with a prolonged marking.

88. In a facsimile-telegraph, the combination with a stylus-carrier and means for actuating the same, of a message-paper-feed roller, a ratchet-wheel mounted in connection therewith, an armature-lever carrying means for turning the ratchet a specific number of teeth, magnets for actuating the said armature-lever, and means governed by the stylus-carrier for energizing said magnets.

89. In a facsimile-telegraph, the combination with a stylus-carrier and means for actuating the same, of a message-paper-feed roller, an armature-lever mounted in relation thereto; means upon and in connection with the said armature-lever and the said feed-roller, whereby the movement of the armature-lever will turn the roller, and electromagnetic means for actuating the said armature-lever.

90. In a facsimile-telegraph, the combination with a stylus-carrier and means for actuating the same, of a message-paper-feed roller; an armature-lever mounted in relation thereto, means upon and in connection with the said armature-lever and the said feed-roller, whereby the movement of the stylus-carrier will turn the roller, a magnet adapted to actuate the said armature-lever and comprised in an electric circuit, and means carried by the stylus-carrier for closing the said circuit.

91. In a facsimile-telegraph, the combination with a stylus-carrier and means for actuating the same, of a message-paper-feed roller; means comprised in an electric circuit for turning the said roller; means controlled by the stylus-carrier for closing the circuit; a relay governing the closing of said circuit, and means for retarding the action of the relay.

92. In a facsimile-telegraph, the combination with a stylus-carrier and means for actuating the same, of a message-paper-feed roller, gear connections upon the said roller, means for disconnecting the gears; a ratchet-wheel connected with said gears, an armature-lever provided with a pawl adapted to turn the said ratchet-wheel, and electromagnetic means for actuating the said armature-lever.

93. In a facsimile-telegraph, the combination with a stylus-carrier, means for moving the same, over a line of the message, and means for reversing the movement of the stylus-carrier, of a message-paper-feed roller, means for turning the same; means comprised in an electric circuit for actuating the stylus-carrier-reversing means, and means comprised in the said circuit for actuating the feed-roller-turning means.

94. In a facsimile-telegraph, the combination with a stylus-carrier, means for moving the same over a line of the message, and means for reversing the movement of the stylus-carrier of the message-paper-feed roller, means for turning the same; means comprised in an electric circuit for actuating the stylus-carrier-reversing means and means carried by the stylus-carrier for controlling the said circuit.

95. In a facsimile-telegraph, the combination with a rotary shaft a stylus-carrier mounted thereon, a shifting-shaft connected with the said stylus-carrier to move the same longitudinally, a message-paper-feed roller, and means for turning the same, of means upon and in connection with the stylus-shaft for stopping and starting the carrier at intervals, means upon and in connection with the said shaft for actuating the shifting-shaft at intervals; means comprised in an electric circuit for reversing the said shifting-shaft, means comprised in the said circuit for actuating the feed-roller-turning

means, and means carried by the stylus-carrier for closing the said circuit.

of opposite polarity; local circuits including respectively the sets or series of recording-stylus devices, a main line connecting with the

vices, relays connected with the main circuit and adapted to be actu-

strip corresponding to the length of continuous travel or stroke of a

means, and means carried by the stylus-carrier for closing the said circuit.

96. In a facsimile-telegraph, transmitting-stylus devices separated in sets or series connected with sources of electrical energy of opposite polarity, recording-stylus devices similarly separated in sets or series, means for sending an impulse from one set of transmitting-styluses when the opposite styluses are in contact with message matter, and means for causing the said impulses to actuate recording-styluses corresponding in position to the contacting transmitting-styluses.

97. In a facsimile-telegraph, transmitting-stylus devices separated in sets or series of opposite polarity, recording-stylus devices similarly separated in sets or series, and means whereby the contacting transmitting-stylus will send to the corresponding recording-styluses an impulse initially of opposite polarity to the transmitting-stylus.

98. In a facsimile-telegraph, transmitting-stylus devices separated in sets or series connected with sources of electrical energy of opposite polarity; recording-stylus devices similarly separated in sets or series; means for sending an impulse from one set of transmitting-styluses when the opposite styluses are in contact with message matter, and devices of opposite polarity between the transmitter and recorder for conveying the transmitting impulse to the corresponding recording-stylus.

99. In a facsimile-telegraph, transmitting-stylus devices separated in sets or series connected with sources of electrical energy of opposite polarity; recording-stylus devices similarly separated in sets or series, means for sending impulses from one set of transmitting-styluses when the opposite styluses are in contact with message matter, means for causing the said impulse to actuate recording-styluses corresponding in position to the contacting transmitting-styluses, and means for sending an impulse to each contacting recording-stylus when both contacting transmitting-styluses are in contact with message matter.

100. In a facsimile-telegraph, transmitting and recording stylus devices included in local circuits, a main line connecting the same, means governed by the transmitting-styluses for sending impulses from their local circuit over the main line to the recording-stylus circuit, and means governed by the said writing impulses for actuating the local recording-circuit to operate the contacting recording-styluses.

101. In a facsimile-telegraph, transmitting and recording stylus devices included in local circuits, a main line connecting the same, means governed by the transmitting-styluses for sending impulses from their local circuit over the main line to the recording-stylus circuit, means governed by the said writing impulses for actuating the local recording-circuit to operate the contacting recording-stylus, and means included in the main line for maintaining a weak current over the line.

102. In a facsimile-telegraph, transmitting and recording stylus devices, each divided into two sets or series; a local circuit including the transmitting-styluses and including sources of electrical energy of opposite polarity; local circuits of opposite polarity including respectively the sets or series of recording-stylus devices, a main line connecting with the transmitter local circuit to receive impulses of opposite polarity therefrom, and devices in the main line connecting with the respective recorder-circuits to cause the same to actuate a contacting recording-stylus when the impulse initiated by the corresponding transmitting-stylus passes over the line.

103. In a facsimile-telegraph, transmitting and recording stylus devices, each divided into two sets or series; a local circuit including sources of electrical energy of opposite polarity; local circuits of opposite polarity including respectively the sets or series of recording-stylus devices, a main line connecting with the transmitting local circuit to receive impulses of opposite polarity therefrom, and relays of opposite polarity included in the main line and adapted to actuate respectively the recorder-circuits.

104. In a facsimile-telegraph, transmitting and recording stylus devices, each divided into two sets or series; a local circuit including the transmitting-styluses and including sources of electrical energy of opposite polarity; local circuits including respectively the sets or series of recording-stylus devices, a main line connecting with the transmitting local circuit to receive impulses of opposite polarity therefrom, means in the main line for actuating the recorder-circuits, and a relay connecting with the main line and adapted to actuate both recorder-circuits when no current passes over the line during the operation of the devices.

105. In a facsimile-telegraph, transmitting and recording stylus devices, each divided into two sets or series; a local circuit including the transmitting-styluses and including sources of electrical energy of opposite polarity; local circuits including respectively the sets or series of recording-stylus devices, a main line connecting with the transmitting local circuit to receive impulses of opposite polarity therefrom, a relay connecting with the main line and adapted to actuate both recorder-circuits when no current passes over the line during the operation of the device, and a relay included in the main line and adapted to maintain a constant weak current over the line between each writing impulse.

106. In a facsimile-telegraph, transmitting and recording stylus devices, each divided into two sets or series; a local circuit including sources of electrical energy of opposite polarity; local circuits including respectively the sets or series of recording-stylus devices, a main line connecting with the transmitting local circuit to receive impulses of opposite polarity therefrom, a relay connecting with the main line and adapted to actuate both recorder-circuits when no current passes over the line during the operation of the device, and a relay included in the main line and adapted to maintain a constant weak current over the line between each writing impulse, said relay being actuated by the writing impulses and comprising means whereby it will send over the line impulses of opposite polarity.

107. In a facsimile-telegraph, transmitting and recording stylus devices, each divided into two sets or series, a local circuit including the transmitting-stylus devices and including sources of electrical energy of opposite polarity; local circuits including the respective sets of the recording-stylus devices; means for short-circuiting one or both sets of the transmitting-styluses; a main line connecting the transmitting and recording circuits, relays of opposite polarity connected with the said main line and with the respective recorder-circuits and adapted to actuate the recorder-circuits to operate their stylus devices, and means for actuating both recorder-circuits when both of the transmitting-stylus devices are short-circuited.

108. In a facsimile-telegraph, transmitting and recording stylus devices, each divided into two sets or series, a local circuit including the transmitting-stylus devices and including sources of electrical energy of opposite polarity; local circuits including the respective sets of the recording-stylus devices; means for short-circuiting one or both of the transmitting-styluses; a main line connecting the transmitting and recording circuits, and relays of opposite polarity connected with the main line and with the respective recorder-circuits and adapted to actuate the recorder-circuits to operate their stylus devices.

109. In a facsimile-telegraph, transmitting and recording stylus devices, each divided into two sets or series, a local circuit including the transmitting-stylus devices and including sources of electrical energy of opposite polarity; local circuits including the respective sets of the recording-stylus devices; means for short-circuiting one or both of the transmitting-styluses; a main line connecting the transmitting and recording circuits, relays of opposite polarity connected with the main line and with the respective recorder-circuits and adapted to actuate the recorder-circuits to operate their stylus devices; and relay included in the main line and adapted to maintain a constant weak current over the line between each writing impulse.

110. In a facsimile-telegraph, transmitting and recording stylus devices, each divided into two sets or series, a local circuit including the transmitting-stylus devices and including sources of electrical energy of opposite polarity; local circuits including the respective sets of the recording-stylus devices; means for short-circuiting one or both of the transmitting-styluses; a main line connecting the transmitting and recording circuits, relays of opposite polarity connected wth the main line and with the respective recorder-circuits and adapted to actuate the recorder-circuits to operate their stylus devices, and a neutral relay connected with the main line and adapted to acuate both the recorder-circuits when there is no current passing over the line.

111. In a facsimile-telegraph transmitting and recording stylus devices connected by suitable circuits and adapted to work in unison, message-paper-feed mechanism mounted in relation to each of the stylus devices; means comprised in an electric circuit for operating the message-paper-feed mechanism said circuits being connected to the main circuit which connects the transmitting and recording devices and relays connected with the main circuit and adapted to be actuated by writing impulses from the transmitting-styluses to operation of the message-paper-feed mechanism.

112. In a facsimile-telegraph, transmitting and recording stylus devices connected by suitable circuits and adapted to work in unison, message-paper-feed mechanism mounted in relation to each of the stylus devices; means comprised in an electric circuit for operating the message-paper-feed mechanism, said circuit being connected to the main circuit which connects the transmitting and recording devices, relays connected with the main circuit and adapted to be actuated by writing impulses from the transmitting-styluses to operate a message-paper-feed mechanism, means for retarding the action of the said relays, and means controlled by the transmitting-styluses for sending a prolonged impulse to actuate the said relays.

113. In a facsimile-telegraph, transmitting and recording stylus devices connected by a main line, means for actuating said styluses; devices for stopping the same, electromagnetic devices for releasing the said stylus devices, a short circuit connected with the said electromagnetic devices, and means actuated by the stopping devices for opening the said short circuit and energizing the said electromagnetic devices.

114. In a facsimile-telegraph transmitting and recording stylus devices connected by a main line; means for actuating the said styluses; devices for stopping the same, electromagnetic devices for releasing the said stylus devices, a short circuit connected with the said electromagnetic devices, means actuated by the stopping devices for opening the said short circuit and energizing the said electromagnetic devices, a second short circuit connected with the first and governed by a relay, and means controlled by the transmitting-stylus devices for opening the latter short circuit and for closing it at intervals.

115. A facsimile-telegraph, comprising rotary stylus-carriers, carrying respectively transmitting and recording styluses; means for actuating the same; message-paper-feed mechanism; means for advancing the same to present successive lines of the message; means for stopping and starting the devices in unison; means for actuating the stylus-carriers to travel over a line of the message; means comprised in an electric circuit for actuating the advancing means of the message-paper-feed mechanism; means for preventing the actuation of the starting devices and means carried by the transmitting-stylus carrier and whereby the feed-roller-turning devices will be actuated and whereby the said devices will be withheld from action during the turning of the message-paper-feed mechanism.

116. In a facsimile-telegraph, the combination with a stylus-carrier means for rotating the same, a message-paper-feed mechanism, means comprised in an electric circuit for operating the said feed mechanism, of a brush carried by the stylus-carrier and means whereby the circuit of the turning devices will be closed when the brush is in prolonged contact with matter upon the message-paper.

117. In a facsimile-telegraph, the combination with the stylus-carrier, means for rotating the same, a message-paper-feed mechanism, and means comprised in an electric circuit for operating the feed mechanism, of a brush carried by the stylus-carrier, means whereby the circuit of the turning devices will be closed when the brush is in prolonged contact with the matter upon the message-paper, and means comprised in the said circuit for reversing the movement of the stylus-carrier.

118. In a facsimile-telegraph, the combination with transmitting and recording stylus devices, and a main line connecting them of governing devices in connection with one of the said stylus devices, comprising a plurality of stripe or surfaces separated by spaces, and contact devices therefor, and means for passing the writing impulses through the said governing devices, whereby the amount of travel of the recording-stylus devices will be restricted to the width of one strip, the said stripe being of a predetermined width corresponding to the predetermined length of continuous travel or successive strokes of the transmitting-stylus devices.

119. In a facsimile-telegraph, the combination with transmitting and recording stylus devices, of governing devices comprising one or more stripe corresponding to one or more transmitting-styluses and of an individual predetermined width corresponding with the length of continuous travel or strokes of a stylus, and the said strip or stripe being succeeded or followed each by a space corresponding to the extent of travel of the stylus devices during the intervals between message impulses.

120. In a facsimile-telegraph the combination with transmitting and recording stylus devices, rotary shafts on which they are mounted, and a main line connecting the devices of means upon the recording-shaft, governed by the writing impulses over the line for causing the said shaft to travel specific distances each corresponding to the length of continuous travel or successive strokes of a transmitting-stylus during a writing impulse.

121. In a facsimile-telegraph the combination with transmitting and recording stylus devices, rotary shafts on which they are mounted, a main line connecting the devices, of magnetic devices in connection with the recorder-shaft comprising separate stripe or surfaces energized by the writing impulses over the line and adapted when energized to prevent rotation of the recorder-shaft after it has rotated a specific distance during a writing impulse the width of the strip corresponding to the length of continuous travel or stroke of a stylus.

122. In a facsimile-telegraph the combination with transmitting and recording stylus devices, rotary shafts on which they are mounted, a main line connecting the devices of a cylinder comprising a plurality of stripe and electromagnetic means upon the recorder-shaft adapted to be attracted by the said stripe to prevent rotation of the shaft a distance greater than the width of a strip during a writing impulse, and means for energizing the same by a contacting impulse.

123. In a facsimile-telegraph the combination with transmitting and recording stylus devices, and a main line connecting the devices, of a device comprising a plurality of separated strips and electromagnetic means upon the recorder-shaft adapted to be attracted by the said stripe to prevent rotation of the shaft a distance greater than the width of a strip during the writing impulse, and means for energizing the same by a contacting impulse.

124. In a facsimile-telegraph, the combination with transmitting and recording stylus devices, rotary shafts on which they are mounted, and a main line connecting the devices, of a cylinder comprising a plurality of strips, and magnetic armatures or fingers having tapered ends adapted to be attracted by the said strips to prevent the rotation of the shaft a distance greater than the width of a strip during a writing impulse.

125. In a facsimile-telegraph, the combination with transmitting and recording stylus devices, rotary shafts on which they are mounted, and a main line connecting the devices of a cylinder surrounding the recorder-stylus shaft and comprising a plurality of longitudinal strips proportioned in number to the styluses, an insulating-spool surrounding the recorder-shaft, wire coils upon the same, connections from the main line to the said coils whereby they are energized by a writing impulse, and tapered armatures or fingers mounted upon the recorder-shaft and adapted to be attracted by the strips to regulate the travel of the recorder-shaft during a writing impulse.

126. A facsimile-telegraph, comprising means for holding a message-sheet, a plurality of styluses arranged to travel transversely over a single line of the message, means for causing successive lines of the message to be traversed by the styluses, and means for causing the styluses to travel in opposite directions over the alternate lines, means comprised in a single electric circuit for actuating the means for presenting successive lines and the stylus-alternating means; and means controlled by the said styluses for governing the said circuit.

127. In a facsimile-telegraph, comprising means for holding a message-sheet, a plurality of styluses arranged in circular series; means for causing the styluses to travel in a vertical plane whereby successively to contact with the message-sheet, means for moving said styluses over a single line of the message, means for causing successive lines of the message to be traversed by said styluses, means for causing the styluses to travel in opposite directions over the alternate lines, means comprised in a single electric circuit for actuating the means for presenting successive lines and the stylus-alternating means, and means controlled by the said styluses for governing the said circuit.

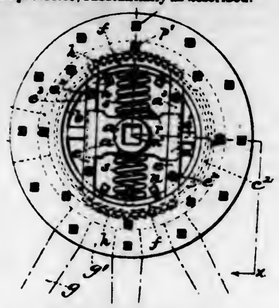
128. In a facsimile-telegraph, a stylus-carrier means for actuating the same, means for stopping the same intermittently a magnet mounted adjacent said stopping devices, an armature-lever mounted in relation to the magnet and comprising means for engaging the stopping devices, and means upon and in connection with the armature-lever whereby the engagement of the stopping device will initiate the energizing of the magnet to attract the said armature-lever and release the sylus-carrier.

812,143. **SPRING-HUB FOR VEHICLES.** WILLIAM M. LEYPORT, Providence, R. I., assignor of one-half to Emmett Ainley, Providence, R. I. Filed Sept. 30, 1905. Serial No. 279,218.

Claim.—1. In a yielding or resilient hub for vehicle-wheels, the combination of a non-revoluble circular frame, a spring-pressed axle-skein movably mounted and guided therein, a plurality of ball-holders adjustably mounted in the outer periphery of said frame, a flanged revoluble ring located outside of and concentric with said frame member having its inner face provided with a peripheral groove or seat and arranged to be secured to the spokes of the wheel, and anti-friction-balls revolubly mounted in said holder members and bearing against the said grooved portion of the revoluble ring, substantially as described.

2. In a spring-hub of the character described, the combination with a stationary circular frame, antifriction-balls adjustably mounted therein and a vertically-movable spring-pressed axle-skein also

supported and guided in said frame, of a revoluble ring member c arranged outside of and concentrically with said frame having its inner or concave face provided with a circumferential groove adapted to form a seat for said balls, and side plates d secured to and revoluble with said ring and extending toward the center of the hub to form a dust-guard and protector, substantially as described.



812,144. DUMB-BELL. ALEXANDER W. MACKENZIE and JAMES ROSS, Edinburgh, Scotland, assignors of one-third to John Gill, Edinburgh, Scotland. Filed Sept. 6, 1904. Serial No. 223,420.

Claim.—1. A dumb-bell comprising an air-tight inflatable body having a central tubular portion and substantially spherical end portions carried thereby, and an inflating and deflating valve, substantially as described.

2. A dumb-bell having a hand portion consisting of an air-tight receptacle made of practically unstretchable flexible material, and an inflating and deflating valve, substantially as described.

3. A dumb-bell consisting of an inner air-tight elastic chamber or receptacle *a*, *b*, an outer cover *d* of practically unstretchable flexible material, an inflating and deflating valve *c* and hollow spheres or balls *e*, combined and arranged substantially as described.

4. A dumb-bell consisting of an air-tight receptacle made of practically unstretchable flexible material, an inflating and deflating valve *c* and hollow metallic spheres or balls *e*, combined and arranged substantially as described.

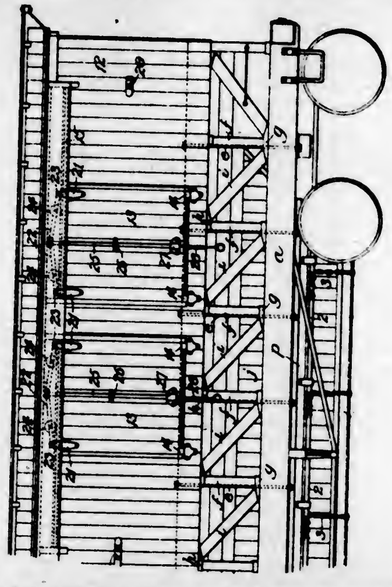
812,145. FREIGHT-CAR. OTTO W. MEISSNER, Chicago, Ill., assignor to Badger Ballast Car Company, Chicago, Ill., a Corporation of Illinois. Filed Mar. 27, 1905. Serial No. 252,574.

Claim.—1. In a freight-car, the combination of side trusses extending longitudinally of the car and forming portions of side frames which extend above such trusses, end frames, side doors mounted above such trusses in the side frames, a hopper-bottom mounted between such side trusses, and dumping-door mechanism for dumping the load from such hopper.

2. In a freight-car, the combination of side trusses extending longitudinally of the car, side frames extending above and having their lower portions formed by such trusses, end frames, a roof supported by such side and end frames, doors mounted in the side frames between the top of the trusses and the roof, and a hopper mounted between such trusses and end frames and provided with dumping-door mechanism for dumping the load from such hopper.

3. In a freight-car, the combination of side trusses extending longitudinally of the car and forming portions of side frames which extend above such trusses, side doors mounted above such trusses in the side frames, a hopper-bottom mounted between the side trusses and provided with dumping-door mechanism, and transverse frame mechanism extending across the car and secured to the upper members of the side trusses and the upper portion of the side frames.

4. In a freight-car, the combination of side trusses extending longitudinally of the car and forming portions of side frames which extend above such trusses, end frames, doors mounted in the side frames above the side trusses, a hopper-bottom mounted between the side trusses and provided with dumping-door mechanism, a central longitudinal sill mounted between the side portions of the hopper, and stay-rod mechanism mounted upon such longitudinal sill and secured to the hopper sides.



5. In a freight-car, the combination of side trusses extending longitudinally of the car, side frames extending above and having their lower portions formed by such trusses, end frames, a roof supported by such side and end frames, doors mounted in the side frames between the top of the trusses and the roof, a hopper mounted between such trusses and end frames and provided with dumping-door mechanism for dumping the load from such hopper, and transverse frame mechanism extending transversely across the car and secured to the top plates of the side trusses and the upper portion of the side frames.

6. In a freight-car, the combination of side trusses extending longitudinally of the car and forming portions of side frames which extend above such trusses, end frames, side doors mounted above such trusses in the side frames, a hopper-bottom mounted between such side trusses, dumping-door mechanism for dumping the load from such hopper, and lining portions secured to the inner side of such side trusses and extending above the upper edges of the hopper flush with the inner surfaces of the hopper sides.

7. In a freight-car, the combination of side trusses extending longitudinally of the car, side frames extending above and having their lower portions formed by such trusses, end frames, side doors mounted above the side trusses in the side frames, a hopper-bottom having inclined side portions extending downward between the side trusses toward the center of the car, and a dumping-door mounted upon such hopper and provided with a slot at its lower edge for receiving the lower edge of the opposite inclined side hopper portion.

8. In a freight-car, the combination of side trusses extending longitudinally of the car, side frames extending above and having their lower portions formed by such trusses, end frames, side doors mounted above the side trusses in the side frames, a hopper-bottom having inclined side portions extending downward between the side trusses toward the center of the car, a dumping-door for such hopper provided with an angle-iron mounted upon its lower edge movable into and out of engagement with the lower outer surface portion of the opposite inclined hopper side, and means for operating such dumping-door.

812,146. METHOD OF PRODUCING TUBES. GEORGE B. MELLINGER, Scottdale, Pa., assignor of two-thirds to Robert Stamp and Joseph R. Stauffer, Scottdale, Pa. Original application filed Oct. 20, 1904. Serial No. 229,243. Divided and this application filed Jan. 23, 1905. Serial No. 242,697.

Claim.—1. That improvement in the art of tube-making which consists in bending the skelp into tubular form with its longitudinal edges opposed, flexing the skelp to present its edges out of coincidence, and contracting the tube to lap the edges of the skelp.

2. That improvement in the art of tube-making which consists in bending the skelp into cylindrical form with its longitudinal edges opposed, flexing one edge inwardly by radial pressure to present its edges out of coincidence, and uniformly contracting the tube by the application of radial pressure at a plurality of diametrically-opposed points.

3. That improvement in the art of tube-making which consists in bending the skelp into tubular form with its edges lapped, and thereafter expanding the tube to present the longitudinal edge faces of the skelp in abutting relation to each other.

4. That improvement in the art of tube-making which consists in bending the skelp into tubular form with its edges lapped, expanding the tube to present the edges out of lapping relation, and flexing the inner edge outwardly by the application of sufficient force to partially counteract its inward stress while insuring the apposition of the edge faces of the skelp when the flexing pressure is relieved.

5. That improvement in the art of tube-making which consists in bending the skelp to the form and dimensions of the finished tube, contracting the tube into convolute form, and expanding the tube to its original form.

6. That improvement in the art of tube-making which consists in bending the skelp into convolute form and thereafter expanding the tube into cylindrical form with the longitudinal edge faces of the skelp abutting each other.

7. That improvement in the art of tube-making which consists in bending the skelp into convolute form, expanding the tube into cylindrical form, flexing outwardly that edge of the skelp having the greatest inward stress, and relieving the flexing pressure to permit the flexed edge of the skelp to spring back into the plane of the cylindrical tube.

8. That improvement in the art of tube-making which consists in bending the skelp into cylindrical form, flexing one edge only of the skelp inwardly, contracting the tube into convolute form, and expanding the tube to cylindrical form, substantially as and for the purpose specified.

9. That improvement in the art of tube-making which consists in bending the skelp into cylindrical form, inwardly flexing one edge of the skelp, contracting the tube into convolute form, expanding the tube into cylindrical form, outwardly flexing the edge previously flexed inwardly, and permitting the flexed edge to spring back to complete the formation of a cylindrical butt-joint tube, all substantially as and for the purpose specified.

10. That improvement in the art of tube-making which consists in bending the skelp into cylindrical form, flexing one edge inwardly by the application of radial pressure thereto, contracting the tube to cause the overlapping of its edges, expanding the tube to present the edges thereof out of lapping relation, and flexing the inner edge outwardly by the application of radial pressure to partially counteract its inward stress while insuring the apposition of the edge faces of the skelp when the flexing pressure is relieved.

11. That improvement in the art of tube-making which consists in bending the skelp to the form of a tube having its edges lapped, urging the inner edge outwardly beyond a point opposite the other edge, and releasing the outwardly-urged edge to permit the same to spring back into abutting relation with the other edge of the skelp to complete the formation of a butt-joint tube.

12. That improvement in the art of tube-making which consists in urging the inner edge of a lap-joint tube outwardly beyond a point opposite the other edge to partially counteract the inward stress of the outwardly-urged edge, and in releasing said outwardly-urged edge to permit the same to spring back into abutting relation with the other edge to form a butt-joint tube.

812,147. APPARATUS FOR MOLDING MATERIALS WHICH SET BY THE ADDITION OF WATER THERETO. JOHN A. MCCONNELL, Allegheny, Pa., assignor to McConnell Asbestos & Covering Co., Pittsburg, Pa., a Corporation of Pennsylvania. Original application filed Apr. 27, 1901, Serial No. 57,809. Divided and this application filed Feb. 23, 1904. Serial No. 194,809.

Claim.—1. In apparatus for wetting, mixing and molding materials which set by the addition of water thereto, the combination with mechanism for wetting and mixing the material, of a series of traveling molds for receiving the wet material from the mixer, and a tilting overflow-trough located beneath the molds at the discharge end of the mixer for receiving the overflow from the molds.

2. In apparatus for wetting, mixing and molding materials which set by the addition of water thereto, the combination with mechanism for wetting and mixing the material, of a chute for conveying the wet material from the mixer, a series of molds adapted to pass underneath the chute and receive the material therefrom, a sleeking device adjacent the chute, and an overflow trough or reservoir underneath the molds below the chute for receiving and storing the overflow from the molds.

3. In apparatus for molding materials which set by the addition of water thereto, the combination of a traveling series of trough-shaped molds, and cores for said molds arranged longitudinally of said molds and lying centrally therein and which automatically swing out of and into said molds under the influence of gravity.

4. In apparatus for molding materials which set by the addition of water thereto, the combination of traveling chains, trough-shaped molds carried thereby, and removable cores for the molds pivoted with relation thereto and arranged to lie centrally within the outer faces of the molds.

5. In apparatus for molding materials which set by the addition of water thereto, the combination of traveling chains, trough-shaped molds carried thereby, longitudinal core-pieces for said molds, and arms on said core-pieces pivoted with relation to and arranged to lie centrally within the outer faces of the molds.

6. In apparatus for molding materials which set by the addition of water thereto, the combination of molds having open ends, removable cores therefor, and plates attached to said cores the edges of which fit the inner surfaces of the molds, thereby forming removable ends for the molds.

7. In apparatus for molding materials which set by the addition of water thereto, the combination of traveling chains, open-ended molds carried thereby, removable cores for said molds, end pieces at-

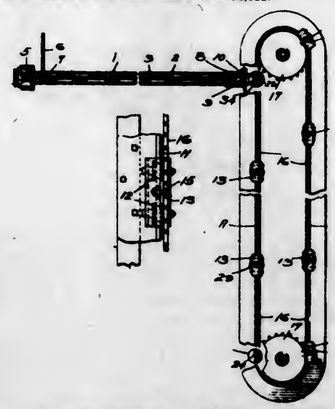
tached to said cores, and means for pivotally securing the cores with relation to the molds.

8. In apparatus for molding materials which set by the addition of water thereto, the combination of traveling chains, molds carried thereby, a receiving table or belt, inclined rods attached to the traveling chains, and connections between said rods and the molds whereby the latter automatically slide down the inclined rods in close proximity to the receiving table or belt and automatically slide back into position on the chains.

9. In apparatus for molding materials which set by the addition of water thereto, the combination of traveling chains, open-ended molds carried thereby, a receiving table or belt, and inclined rods attached to the chains and having the molds slidably connected thereto, said rods being wider apart at their outer ends whereby the molds will automatically slide down the inclined rods in close proximity to the receiving-belt and be slightly spread thereby.

10. In apparatus for molding materials which set by the addition of water thereto, the combination of traveling chains, molds carried thereby, a receiving table or belt, inclined rods attached to the chains, a stop or projection on the free end of said rods, and connections between the molds and said rods whereby the former can automatically slide down said rods into close proximity to the receiving-belt and contact with said stop or projection.

812,148. APPARATUS FOR MOLDING PLASTIC MATERIAL. JOHN A. MCCONNELL, Allegheny, Pa., assignor to McConnell Asbestos & Covering Co., Pittsburg, Pa., a Corporation of Pennsylvania. Original application filed July 18, 1903, Serial No. 166,067. Divided and this application filed Feb. 23, 1904. Serial No. 194,811.



Claim.—1. In apparatus for molding in a substantially liquid condition materials which set by the addition of water thereto, the combination with mixing and wetting apparatus having a discharge-opening, of an endless series of tight-bottomed molds, and mechanism for carrying the said molds in succession underneath the discharge-opening of the mixing and wetting apparatus.

2. In apparatus for molding in a substantially liquid condition materials which set by the addition of water thereto, the combination with mixing and wetting apparatus, of an endless series of molds having tight bottoms, means for delivering the material from the mixer, and mechanism for giving an intermittent travel to said molds and carrying the same in succession underneath said delivering means.

3. In apparatus for molding in a substantially liquid form materials which set by the addition of water thereto, the combination of a series of vertical molds each composed of two sections hinged together and having tight bottoms, means for locking the said sections together, suspending means connected to the bottoms of said molds, and an overhead carrier to which said suspending means are connected.

4. In apparatus for molding articles from materials which set by the addition of water thereto, the combination of a series of molds, an overhead track, trolleys thereon from which the molds are suspended, an endless chain, and connecting means between the same and said trolleys.

5. In apparatus for molding articles from materials which set by the addition of water thereto, the combination of a series of molds, an overhead track, trolleys on said track from which the molds are suspended, an endless chain, connections between the same and the trolleys, sprocket-wheels around which said chain passes, and driving means connected to one of said sprockets.

6. A mold for forming articles from materials which set by the addition of water thereto comprising two vertically-arranged sections hinged together, fastening means for said sections, and a support therefor, and suspending means connected to said support.

7. A mold of the character described comprising two vertically-arranged sections hinged together, fastening means therefor, a core in said mold, and a support for said molds and core, and suspending means connected to said support.

8. A mold of the character described comprising two vertically-arranged sections hinged together, fastening means for the same, a base upon which the same are supported, and a core connected to said base, and suspending means connected to said base.

9. A mold of the character described comprising two vertically-arranged sections hinged together, fastening means therefor, a base therefor, a core supported in said mold, and suspending means attached to said base.

10. A mold of the character described comprising two vertically-arranged sections, means for securing the same together, and a core arranged vertically in the center of said molds and provided with oppositely-arranged wings, one of said wings extending out to and connecting with the mold, and the other of said wings being narrower.

11. A mold of the character described comprising two vertically-arranged sections, means for securing the same together, a base therefor, a core arranged vertically in said mold and supported on said base, and a funnel resting on said mold and provided with means for centering the upper end of said core.

812,149. TAPE-HOLDER. JOHN MCLEAN, Newark, N. J., assignor to The Whitehead & Hoag Company, Newark, N. J., a Corporation of New Jersey. Filed Oct. 3, 1902. Serial No. 126,530.

Claim.—1. In a tape-holder, a shell having a flaring open end, in combination with a cup-shape disk fitting over and upon the flaring open end of the shell and provided with a covering of celluloid having its edges crimped over the edges of the disk and between said edges and the flaring end of the shell.

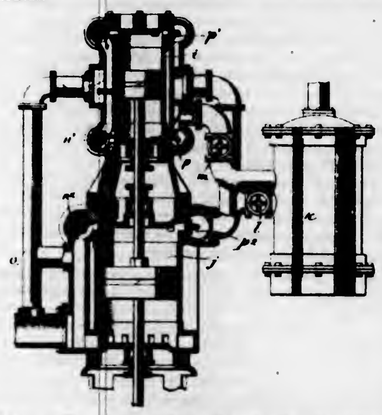
2. In a tape-holder, a shell having one end formed with an annular bead or shoulder, a metal disk covering the open end of the shell and having an annular flange encircling the bead, and a second disk of celluloid applied to the outer face of the first-named disk and having its marginal edge crimped over the edge of the flange and adjacent bead to lock the disks to the shell.

3. A tape-holder comprising a circular shell, a spring-actuated drum arranged within said shell, a tape winding around said drum and projecting through a slot in the shell, said shell being provided with a beaded edge, a metallic disk having an inturned flange on its edge adapted to loosely inclose the beaded edge of said shell and a non-metallic covering having a flanged edge crimped around the inturned edge of said disk, and filling the space between the inside of the flange of the disk and the outer wall of the said shell.

812,150. TAPE-MEASURE. JOHN MCLEAN, Newark, N. J., assignor to The Whitehead & Hoag Company, Newark, N. J., a Corporation of New Jersey. Filed June 10, 1904. Serial No. 211,862.

Claim.—In a device of the character described, the combination of a circular band 1, the disk 8 having inturned marginal flanges 9 embracing the edge of said band, the plate 11 having its edge interposed between the edge of the band and the said disk 8, the hub 12 carried by said plate, the celluloid covering 16 having its marginal edge turned over upon the marginal flange of said disk, the reel 6 mounted on said hub, the tape 5 wound on said reel, the ring 13 having an inturned marginal edge, and the celluloid covering 16 having its marginal edge turned over and inwardly upon the inturned edge of said plate 13, substantially as described.

812,151. FLUID-OPERATED ENGINE. BRUNO V. HORSTMAN, Milwaukee, Wis. Original application filed Sept. 13, 1902, Serial No. 173,691. Divided and this application filed Nov. 20, 1904. Serial No. 234,757.



Claim.—1. In an engine adapted to deliver a blow, the combination of two cylinders; a piston working in each of said cylinders; a piston-rod common to said pistons; means for admitting steam simultaneously and at the same pressure to the upper face of each of said pistons; and means for admitting steam to the under face of one of said pistons while steam is exhausted from the opposite face of each of said pistons.

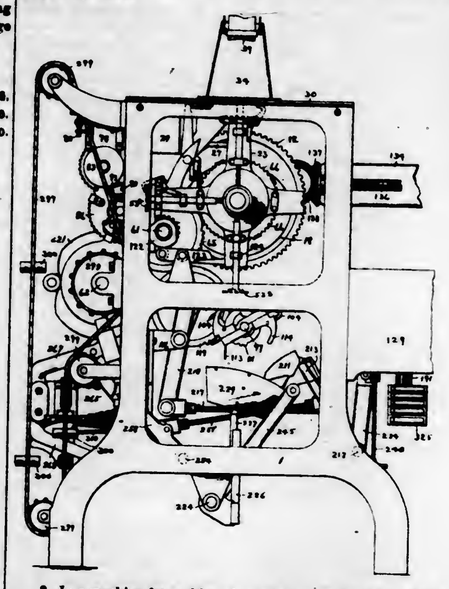
2. In an engine, the combination of a pair of cylinders; a piston working in each of said cylinders; a piston-rod common to said pistons; a receiver; means for delivering steam simultaneously from said receiver to the corresponding end of both cylinders; and means for admitting steam to the opposite end of one of said cylinders while the pistons are moving in the opposite direction.

3. In an engine, the combination of a pair of cylinders; a piston working in each of said cylinders; a piston-rod common to said pistons; a receiver; means for admitting steam from said receiver to the upper end of each of said cylinders; means for admitting steam from said receiver to the lower end of the upper cylinder; and a condenser connected to the lower end of the lower cylinder.

4. In an engine, the combination of a pair of cylinders; a piston working in each of said cylinders; a piston-rod common to said pistons; a receiver; means for admitting steam from said receiver to the upper end of each of said cylinders; means for admitting steam from said receiver to the lower end of the upper cylinder; a condenser connected to the lower end of the lower cylinder and in communication therewith at all times; a valved port affording communication between the lower end of the upper cylinder and the condenser; and a valved port affording communication between the upper end of the lower cylinder and the condenser.

812,152. MACHINE FOR MAKING ALL-TOBACCO CIGARETTES. ALFRED H. RANDALL, Jr., Philadelphia, Pa., assignor of one-half to Pembroke D. Horton, Philadelphia, Pa. Filed Oct. 11, 1904. Serial No. 227,982.

Claim.—1. In a machine for making cigarettes, wrapper-cutting mechanism, rolling mechanism, means for conveying the wrapper to the rolling mechanism, a plurality of scale-beams, filler-receptacles secured to one end of the scale-beams, means for feeding the filler to said scale-receptacles, means for automatically emptying the scale-receptacles simultaneously when all the scale-receptacles are down, means for conveying the filler to the rolling-table, a clutch for controlling the wrapper-cutter, transfer apparatus and rolling mechanism, means for operating said clutch as many times after the scale-receptacles are empty as there are scale-beams less one, and means for arresting the release of the clutch until all of the scale-beams are down, when the clutch will be released automatically, as and for the purpose specified.



2. In a machine for making cigarettes, wrapper-cutting mechanism, rolling mechanism, means for delivering the wrapper to the rolling mechanism, a plurality of scale-beams, filler-receptacles secured upon one end of the scale-beams, means for feeding the filler to each scale-receptacle, means for automatically cutting off the feed from each scale-receptacle as each receptacle is filled with the proper weight of material and descends, means for automatically emptying all the scale-receptacles simultaneously when all of said scale-receptacles have descended, means carrying the filler to the rolling mechanism, an electromagnetic-controlled clutch controlling the wrapper cutting, transferring and rolling mechanism, whereby said parts are operated one step each time the magnets of said clutch are energized, a switch, electric means for energizing the magnets of the clutch by means of the switch as many times after the scale-receptacles are emptied as the total number of scale-receptacles less one, and means for then changing the course of the current so that the clutch-magnets cannot be energized until all of the scale-receptacles are down, thus completing the circuit and energizing the magnets.

3. In a machine for making cigarettes, a clutch, electromagnets controlling said clutch, a wrapper-cutting mechanism, rolling mechanism, means for transferring the wrapper to the rolling mechanism, all of said elements adapted to operate synchronically one step at a time each time the clutch is operated, a plurality of scale-beams, scale-receptacles secured at one end of each beam, an independent feeding mechanism for each scale-receptacle, electromagnetic means for starting the feed when the scale-receptacle is up and stopping the feed when the scale-receptacle is down, means for automatically emptying the scale-receptacles when all of said receptacles are down, a rotating commutator adapted to operate synchronically with the operating mechanism, two contact-points located in juxtaposition to each scale-beam, each set of contact-points being connected to the next set in series, the two contact-points of each set adapted to be connected one with the other when the scale-receptacles are lowered, a switch adapted to be operated by the operator, electrical connections extending from the switch, a commutator and contacts, the conducting-stripe upon the commutator so arranged that the circuit will be established through the switch, commutator and clutch-magnets each time the switch is closed for as many times after the scale-receptacles have been emptied as the total number of said scale-receptacles less one, the circuit then being changed by the commutator so that it must pass through the switch, commutator and all of the contacts of the scale apparatus before the magnets of the clutch can again be energized, as specified.

4. In a machine for making cigarettes, a wrapper-cutting, a wrapper-delivering, a wrapper-pasting, a cigarette-rolling, a ciga-

rette trimming and delivering mechanisms, a series of scale-beams, scale-receptacles secured upon one end of said scale-beams, a feeding mechanism for feeding the filler to the scale-receptacles, means whereby all of the scale-receptacles are emptied when all of the scale-receptacles are down, means for operating the machine synchronically whereby one wrapper is cut, transferred, pasted and one cigarette is rolled, trimmed and delivered each time the machine is operated, means for operating the machine irrespective of the position of the scale-beams as many times after the scale-receptacles have been emptied as there are scale-beams less one, and means for preventing the next movement of the machine until all of the scale-beams are down, as and for the purpose specified.

5. In a machine of the character described, a series of scale-beams, scale-receptacles secured to one end of said scale-beams, an independent feeding mechanism for each scale-beam adapted to feed into the scale-receptacles, means for operating the feeding mechanism consisting of a constantly-rotating member common to all the feeding devices, second members, one for each feeding device and journaled concentric with the rotary member but separate therefrom, driving mechanism connecting each second member with its feeding device, electromagnets arranged upon one of the members, the other member of each feeding device acting as an armature, two contact-points arranged in juxtaposition to each scale-beam, the contact-points of each set adapted to be electrically connected when the scale-receptacle is up and the electrical connection broken when the scale-receptacle is down, a source of electricity, an electric circuit from one terminal of the source of electricity to one of the contacts of each scale-beam, and from the other contact of each scale-beam, to and through the electromagnets of the feeding device of the same scale-beam, back to the other terminal of the source of electricity.

6. In a machine of the character described, a series of scale-beams, scale-receptacles secured to said scale-beams, an independent feeding device for feeding the filler to each scale-receptacle, means for operating said feeding device, consisting of a constantly-rotating shaft, a series of disks, one for each feeding device secured upon said shaft and adapted to rotate therewith, electromagnets carried by said disk, disk-shaped armatures journaled concentric with the rotating shafts but independent thereof, said armatures arranged in juxtaposition to the cores of the magnets, a source of electricity, electric switches adapted to be closed when the scale-receptacles are up, an independent electric circuit for each filling device including in the same the source of electricity of said device, and the electroswitch of its particular scale-beam so that when the electromagnets are energized the armature will be caused to rotate therewith, and means for transmitting the movement of the armatures to the feeding devices independent of one another, as specified.

7. In a machine of the character described, a manufacturing portion, a feeding and weighing portion, a series of scale-beams included in the weighing portion, scale-receptacles secured to the scale-beams adapted to receive filler from the feeding device, a stationary electromagnet arranged in juxtaposition to the scale-beam, an armature carried by the scale-beam, the tendency of the magnet when energized being to hold the scale-receptacle lowered, a commutator adapted to rotate with intermediate movements synchronically with the manufacturing mechanism, there being as many movements in a complete revolution of the commutator as there are scale-beams, said commutator adapted to make one complete revolution between the successive emptying of the scale-receptacles, means for preventing the last movement of the commutator until all the scale-receptacles are lowered, an electric circuit through the magnets adjacent the scale-beam and through the commutator upon this last movement to hold the scale-receptacles down against vibration while said receptacles are emptied, as specified.

8. In a machine of the character described, scale-beams, scale-receptacles carried by said scale-beams, a stationary electromagnet arranged in juxtaposition to the scale-beams, armatures carried by the scale-beams, the tendency of said magnet when energized being to tilt the scale-beam so as to hold the scale-receptacle raised, a commutator adapted to revolve synchronically with the operation of the machine, an electric circuit containing the magnets and certain conducting-strips upon the commutator, said strips so arranged upon the commutator that said magnets will be energized for a short period directly after the scale-receptacles have been emptied, as specified.

9. In a machine of the character described, a series of independent operating scale-beams, scale-receptacles carried by said scale-beams, independent feeding mechanisms for each scale-beam, said feeding mechanism consisting of an endless belt, the filler adapted to lie upon the upper run of said belt, two rollers, one arranged upon the other, the belt at its rearward end adapted to pass around the lowermost roller so that the filler will pass between the upper roller and the belt, a separating-roller arranged at the rear of the two feeding-rollers, picker-teeth protruding from said separating-roller adapted to shred and separate the tobacco as it passes from the belt into the scale-receptacles, means for revolving the feeding-rollers, and means for arresting the movement of said rollers when the scale-receptacle is down, and starting said rollers when the scale-receptacle is up, as and for the purpose specified.

10. In a machine of the character described, a series of independently-operating scale-beams, a scale-receptacle carried by each scale-beam, an independent feeding mechanism for each scale-receptacle, each consisting of two rollers, one arranged above the other a slight distance apart, an endless belt, upon the upper run of which the tobacco is adapted to lie, the rearward end of said belt passing around the lowermost roller, corrugations formed in the periphery of the upper roller, a constantly-revolving separating-roller arranged at the rear of the two feeding-rollers, picker teeth or pins protruding from the periphery of said roller for shredding or separating the tobacco as it issues from the feed-rollers, a chute for conveying the tobacco to the scale-receptacles, driving mechanism for operating the feed-rolls, electrical contacts arranged in juxtaposition to each scale-beam, and electric means for starting the driving mechanism when the contacts are closed and stopping said driving mechanism when the contact is broken, as specified.

11. In a machine of the character described, rolling mechanism, a series of scale-beams, scale-receptacles carried by said scale-beams, feeding mechanism, means for automatically emptying the scale-receptacles when all of them are down, means for carrying the filler to the rolling mechanism consisting of an endless belt, pockets secured to said belt, said belt adapted to be driven synchronically with the movement of the rolling mechanism, said belt arranged so that the pocket is always underneath the scale-receptacles when the same are emptied, as specified.

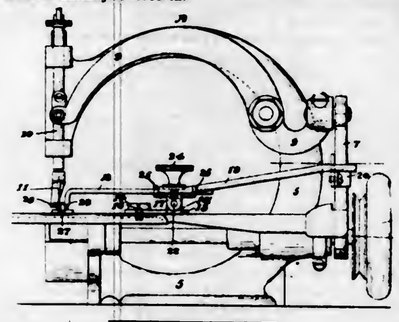
12. In a machine of the character described, in combination, a wrapper-carrier apparatus, consisting of radial arms, flat plates secured to the outer ends of said arms against which the wrapper is held, a pasting mechanism consisting of a rotating member adapted to rotate synchronically with the wrapper-transfer, a lever pivoted to said rotary member upon each side of its pivot, pasting-rolls journaled in one end of the levers, springs secured to the other ends of the levers tending to throw the rollers outward, means for revolving the rollers upon their own axis as the rotary member revolves, said rollers adapted to come in contact with a portion of one end of the wrapper, a paste-roll, a paste-receptacle arranged above the roll, means for revolving the paste-roll in contact with the paste in the receptacle synchronically with the movement of the wrapper-transfer apparatus, the pasting-rolls adapted to come in contact with the paste-rolls as they revolve, as specified.

13. In a machine of the character described, the combination, a wrapper-cutting mechanism and pasting mechanism with a carrier mechanism, consisting of a hub mounted upon a shaft, radial arms extending outward from said shaft, said hub adapted to rotate synchronically with the wrapper cutting and pasting mechanism, rods mounted to slide radially along the radial arms, flat plates secured to the outer ends of said rods, springs tending to force said rods outward, fingers adapted to automatically engage and hold the wrapper to the plates as said wrapper is presented to be pasted, means to be operated at the option of the operator for retracting or pushing inward the radial rod and plate which is presented to the pasting mechanism, as specified.

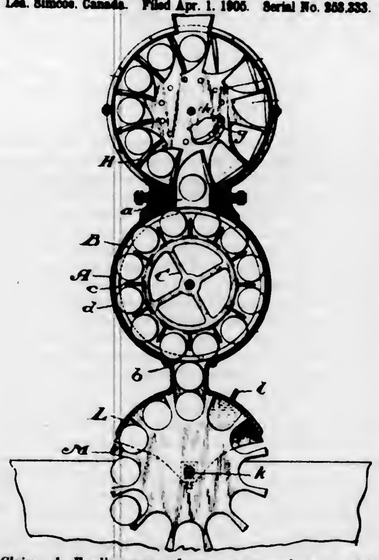
812,153. TRIMMING ATTACHMENT FOR SEWING-MACHINES. WILLIAM B. RISE, Maplewood, N. J., assignor of one-half to Frank Burke, Newark, N. J. Filed Jan. 3, 1905. Serial No. 239,486.

Claim.—1. In a sewing-machine, the combination with the cloth-plate, needle and needle-operating means, of a fulcrum-plate removably seated on said cloth-plate, a fulcrum-pin supported by said fulcrum-plate, a rocking plate arranged on said pin, a slotted shearing-knife extending from said rocking plate to a coöperating knife near said needle, a set-screw arranged in the slot of said knife, a lever-arm also supported by said fulcrum-plate and extending to a slotted bracket, and said slotted bracket attached to a part of the needle-operating means, and said coöperating shearing-knife, substantially as set forth.

2. In a sewing-machine, the combination with the cloth-plate, needle and needle-operating means, of a fulcrum-plate separably attached to the cloth-plate, a rocking plate pivoted on said fulcrum-plate, a slotted shearing-knife adjustably fastened on said rocking plate and turned downward at its free end and sharpened to form a cutting edge, a coöperating cutting-blade fixed upon the cloth-plate, a lever-arm also attached to the rocking plate and extending therefrom to a bracket separably clamped to a part of the needle-operating means, substantially as set forth.



812,154. CONTINUOUS STEAM-COOKER. ROBERT H. SCOTT and LYMAN O. STEINHOFF, Simcoe, Canada; said Scott assignor to Arthur C. Lea, Simcoe, Canada. Filed Apr. 1, 1905. Serial No. 253,333.



Claim.—1. Feeding means for a cannery-cooker comprising a cylindrical casing with inlet and discharge apertures therein, in combination with a steam-tight cylinder journaled therein and provided with peripheral pockets adapted to contain cans; a valve for each pocket pivoted on the cylinder and adapted to open and close the peripheral opening of said pocket; and means for opening each of said valves to receive a can and for closing it immediately after the discharge of a can, substantially as described.

2. Feeding means for a cannery-cooker comprising a cylindrical casing with inlet and discharge apertures therein, in combination with a steam-tight cylinder journaled therein and provided with peripheral pockets adapted to contain cans; valves adapted to open and close the peripheral openings of said pockets; means for opening each of said valves to receive a can and for closing it immediately after the discharge of a can; and means for forming a communication between the outer air and the pocket behind each valve, substantially as described.

3. Discharge means for a cannery-cooker comprising a cylindrical segment-casing with an inlet-aperture at the top, in combination with a steam-tight cylinder journaled therein and provided with peripheral pockets adapted to contain cans and a sufficiency of water to shut out the steam in the cooker; and means for supplying water to each pocket before it reaches the inlet-aperture, substantially as described.

4. Feeding means for a cannery-cooker comprising a cylindrical casing with inlet and discharge apertures therein, in combination with a steam-tight cylinder journaled therein and provided with peripheral pockets adapted to contain cans; a swing-valve pivoted at one side of each pocket near the periphery of the cylinder, the opposite side of the pocket being formed on the arc of a circle struck with the pivot of the valve as a center; and means for opening each of said valves to receive a can and for closing it immediately after the discharge of a can, substantially as described.

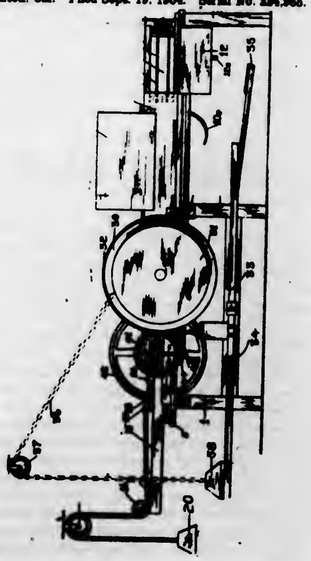
5. A cannery-cooker provided with a receiving-hopper; and an endless conveyer discharging into said hopper and provided with receptacles adapted to receive cans, in combination with a second conveyer parallel to and close beside the first and adapted to bring cans on end; and means timed with the second conveyer for knocking a can off the said conveyer onto its side in one of the receptacles of the first conveyer, substantially as described.

6. Two cannery-cookers, each provided with a receiving-hopper; endless conveyers discharging into the hoppers of the cookers and provided with receptacles adapted to receive cans, in combination with a second endless conveyer leading to a point between the first two; and an arm operated from the second conveyer and adapted to alternately sweep cans onto the two first conveyers, substantially as described.

7. Two cannery-cookers, each provided with a receiving-hopper; endless conveyers discharging into the hoppers of the cookers and provided with receptacles adapted to receive cans on their sides, in combination with a second endless conveyer leading to a point between the first two; an arm operated from the second conveyer and adapted to alternately sweep cans onto the first two conveyers; and bottom stops adapted to catch the bottom edges of the cans to insure their falling on their sides on the conveyers, substantially as described.

8. Two cannery-cookers, each provided with a receiving-hopper; endless conveyers discharging into the hoppers of the cookers and provided with receptacles adapted to receive cans on their sides, in combination with a second endless conveyer leading to a point between the first two; an arm operated from the second conveyer and adapted to alternately sweep cans onto the first two conveyers; bottom stops adapted to catch the bottom edges of the cans to insure their falling on their sides on the conveyers; and guides adjacent to each of the second conveyers adapted to center the cans on the conveyer, substantially as described.

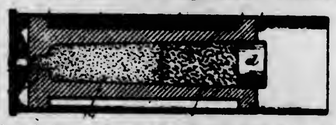
812,155. FIBER-BALING MACHINE. ARTHUR M. SHRADLEY, Stockton, Cal. Filed Sept. 19, 1904. Serial No. 224,968.



Claim.—1. In a device of the kind described, the combination of a suitable frame, a compression-chamber mounted on the frame, a plunger arranged in said compression-chamber, a horizontal shaft mounted on the frame, cones carried by said shaft, a cross-bar attached to the plunger, chains attached to said cross-bar and winding around said cones, a second horizontal shaft mounted on the frame, intermeshing gearing carried by said shafts, a pulley carried by said second shaft, clutch mechanism comprising clutch members carried by said second shaft and said pulley, a lever pivoted on the frame and connected to said clutch mechanism, a spool carried by said first-named shaft, a chain carried by said spool, a weight attached to said chain, a brake-wheel carried by said shaft, a brake-band surrounding said brake-wheel, a pivoted lever attached to said brake-band, said weight being adapted to bear on the end of said pivoted lever to bring the brake-band into contact with the brake-wheel, substantially as described.

2. In a device of the kind described, the combination of a suitable frame, a compression-chamber mounted on the frame, a plunger arranged in the compression-chamber, a horizontal shaft mounted on the frame, a cross-bar attached to the plunger, flexible connections attached to the cross-bar and winding around said shaft, a second horizontal shaft mounted on the frame, intermeshing gearing carried by said shafts, a pulley carried by said second shaft, clutch mechanism carried by said pulley and said second shaft, a lever pivoted on the frame, and connected to said clutch mechanism, a third chain connected to the first-named shaft, a weight attached to said last-named chain, a brake-wheel carried by said first-named wheel, a brake-band surrounding said brake-wheel, a lever pivoted to said brake-band, said weight being adapted to bear on said lever.

812,156. **BLANK SMOKELESS-POWDER CARTRIDGE.** Pim Sparrs, Wilmington, Del. Filed Sept. 13, 1905. Serial No. 278,290.



Claim.—1. A smokeless-powder charge comprising a cartridge-case, a powder-receptacle having rigid walls inserted within the case and held in permanent relation thereto and spaced permanently therefrom to form an air-space between the outer wall of the receptacle and the inner wall of the case.

2. A smokeless-powder charge comprising a cartridge-case, a powder-receptacle having a rigid bottom and rigid walls and held in permanent relation to the case; a charge within the receptacle consisting of powder and a filling material, said charge extending outwardly from the bottom of the receptacle and not exceeding in length that of either the case or the receptacle.

3. A smokeless-powder charge comprising a cartridge-case, a powder-receptacle having rigid walls inserted within the case and held in permanent relation thereto, the interior walls of the receptacle being tapered inwardly toward its lower or inner end.

812,157. **COMBINED ANIMAL TETHER AND FEED-BAG.** Frank H. Thompson, Haw River, N. C. Filed Apr. 1, 1905. Serial No. 253,206.

Claim.—1. A standard adapted at one end for insertion into the ground and with a collapsible feed-receptacle at the other end.

2. A standard formed in two sections, clamping means for movably uniting the adjacent ends of said sections, the free end of one of said standard-sections for insertion into the ground, and a collapsible feed-receptacle connected to the other standard-section.

3. A standard disposed in vertical position, means for tethering an animal to said standard, and a collapsible feed-receptacle attached to said standard.

4. A standard, a frame swinging from said standard, means for supporting said frame at right angles to said standard and a flexible feed-receptacle suspended from said frame.

5. A standard formed in two sections, clamping means for movably uniting the adjacent ends of said sections one of said sections adapted for insertion into the ground, a frame swinging from the other of said standard-sections, supporting means extending between said frame and standard and detachably connected thereto, and a collapsible feed-receptacle suspended from said frame.

7. A standard, a frame swinging from said standard, detachable means for supporting said frame extended from said standard, and a flexible feed-receptacle suspended from said frame.

8. A standard, a frame swinging from said standard, a plate swinging from said standard and spaced from said frame, links movably coupling said frame and plate, means for supporting said plate and the frame coupled thereto in extended position and a flexible feed-receptacle suspended from said frame and bearing upon said plate when distended.

9. A standard, a frame swinging from said standard, a plate swinging from said standard and spaced from said frame, links movably coupling said frame and plate, a brace member swinging from said plate, means for coupling the free end of said brace member detachably to said standard, and a flexible feed-receptacle suspended from said frame and bearing upon said plate when extended.

10. A standard formed in two sections movably united by a clamp-bolt, a frame swinging from one of said standard-sections, and a plate swinging from one of said standard-sections and spaced from said frame, links movably connecting the free ends of said frame and plate, a flexible feed-receptacle suspended from said frame and bearing upon said plate when distended, and a brace member swinging from said plate and engaging said clamp-bolt and held in operative position thereby.

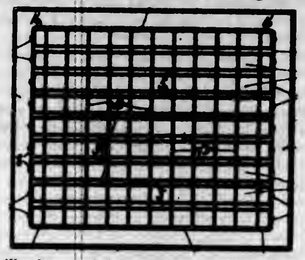
11. A standard formed in two sections having transverse apertures for receiving a clamp-bolt, one of said standard-sections having spaced studs and the other standard-section having spaced recesses for receiving the studs when the standard-sections are disposed in longitudinal alinement, in combination with a collapsible feed-receptacle connected to one of said standard-sections.

12. A standard formed in two sections, clamping means for movably uniting the adjacent ends of said sections, one of said sections adapted for insertion into the ground, and with a laterally-extending stop extending therefrom to limit the movement, in combination with a collapsible feed-receptacle connected to the other standard-section.

812,158. **GRILLE-PLATE.** William S. Tuttle, Brooklyn, N. Y., assignor to Tuttle & Bailey Mfg. Company, Brooklyn, N. Y., a Corporation of New York. Filed Apr. 26, 1904. Serial No. 204,995.

Claim.—1. A sheet-metal grille-plate having a substantially flat marginal flange and alternate bars and slots running from the margin at one side to the margin at the opposite side, the bars having longitudinal reinforcing-flanges provided with transverse apertures, and additional bars running transversely and through the apertures of the first-named bars.

2. A sheet-metal grille-plate having a substantially flat margin and its central body provided with a series of bars and intervening slots both running continuously from the margin at one side to the margin at the opposite side, each bar having parallel reinforcing-flanges depending from its longitudinal edges, said flanges being provided with transverse apertures, and additional straight bars running transversely of the first-named bars and through said apertures.



3. A grille-plate consisting of a sheet-metal body having its central portion provided with parallel bars and intervening parallel spaces, the bars having reinforcing-flanges provided with transverse apertures, and additional bars inserted transversely through said apertures.

4. A grille-plate consisting of a sheet-metal body having its central portion provided with a series of lengthwise bars and intervening lengthwise slots, the portions of the plate at the ends of the slots forming retaining-lugs projecting from the plate, and transverse bars resting in the retaining-lugs.

5. A grille-plate consisting of a sheet-metal body having its central portion provided with a series of lengthwise bars and intervening lengthwise slots, reinforcing-ribs projecting from the longitudinal edges of the bars and provided with transverse apertures, transverse bars running through said apertures, and laterally-projecting shoulders on the transverse bars to prevent their endwise displacement.

6. A grille-plate consisting of a substantially flat margin and a series of bars having their ends united to opposite sides of the margin and their intermediate portions spaced apart to form intervening spaces, said bars having reinforcing-ribs projecting from their longitudinal edges and provided with transverse apertures, transverse bars running through said apertures, additional transverse bars at the ends of the first-named bars, and means for securing the additional transverse bars to the plate.

7. A sheet-metal grille-plate having a series of bars and intervening spaces of substantially the same length as the bars, each bar having a depending flange at each longitudinal edge and of substantially half the width of the adjacent space, said plate having integral retaining-lugs at the end of the spaces, and transverse bars held by said lugs.

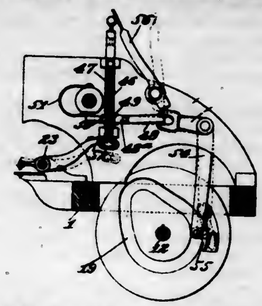
8. A sheet-metal grille-plate having lengthwise-bars and intervening spaces of substantially the same length as the bars, reinforcing-ribs united to the longitudinal edges of said bars, additional bars running transversely at the ends of the first-named bars, said plate having integral lugs at the ends of said spaces and engaging said additional bars to hold them in place.

812,159. **PRESSER-FOOT AND MECHANISM FOR OPERATING THE SAME.** John N. Whipple, St. Louis, Mo., assignor to Landis Machine Company, St. Louis, Mo., a Corporation of Missouri. Filed Feb. 18, 1903. Serial No. 94,397.

Claim.—1. The combination with a presser-foot, of a presser-bar, connection between said presser-foot and presser-bar whereby raising of the latter effects depression of the former and vice versa, a spring 47 tending to raise said presser-bar, a bail 45°, an arm 48 pivoted to said bail, a saddle-block 49, a bail 50, a spring 51, and means coöperating with the outer end of the arm 48 for moving the same and the presser-bar vertically; substantially as described.

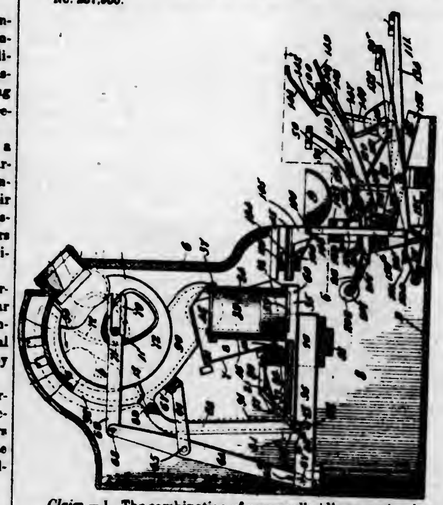
2. The combination with a presser-foot, of a presser-bar to which the same is connected, a clamp on said presser-bar having one member extending rearwardly, a bifurcated arm coöperating with said extended member of the clamp, a cam for rocking said bifurcated arm, and a yielding wall in said cam; substantially as described.

3. The combination with a presser-foot, of a presser-bar to which the same is connected, a clamp coöperating with said bar and having a rearwardly-extending member, a bifurcated arm coöperating with said extended member, one of the jaws of said arm being pivoted, and a lever coöperating with said bifurcated arm to relieve the rearwardly-extending clamp member; substantially as described.



4. The combination with a presser-foot having a rearwardly-extending arm, of a presser-bar having slot connection with said arm, a buffer on the end of said arm, a clamp coöperating with said presser-bar, and means coöperating with said clamp to move the bar vertically; substantially as described.

812,160. **CHANGE-MAKING MACHINE.** Thomas S. Wilkie, Phœnix, Ariz., assignor to The American Patent Promotion Company, Phœnix, Ariz., a Corporation of Arizona. Filed Dec. 22, 1904. Serial No. 237,960.



Claim.—1. The combination of a normally idle operating-key, a coin-deliver controller, a coin-slot guard, and means operated by said guard to connect the said deliverer-controller to said normally idle key for operation thereby.

2. A change-making machine having coin-deliverer controllers, operating-keys, means to connect them to certain of the controllers, and means to throw said keys out of operation and to simultaneously operate certain other of the controllers.

3. A machine of the character described comprising coin-holding means, tilting coin-deliverers, means for feeding coins from said holding means to said deliverers and means for controlling the operation of said coin-deliverers, substantially as described.

4. A machine of the character described comprising coin-holding means, vertically-movable coin-deliverers, means for feeding coins from said holding means to said deliverers, and means for moving said deliverers to an inoperative position, substantially as described.

5. A machine of the character described comprising coin-holding means vertically-movable coin-deliverers, and means for elevating one or more of said deliverers out of the paths of their respective coin-feeding means, substantially as described.

6. A machine of the character described comprising coin-holding means, coin-feeding means, vertically-movable coin-deliverers, and a key-lever for elevating one of said deliverers out of the path of its coin-feeding means, substantially as described.

7. A machine of the character described comprising coin-holding means, coin-feeding means, vertically-movable coin-deliverers, and a key-lever for elevating one or more of said deliverers out of the paths of their respective coin-feeding means, substantially as described.

8. A machine of the character described comprising coin-holders, coin-feeders, movable coin-deliverers, means operated by said coin-feeders for actuating said coin-deliverers, and means for preventing the operation of said coin-deliverers by said coin-feeders, substantially as described.

9. A machine of the character described comprising coin-holders, coin-feeders, movable coin-deliverers, means operated by said coin-feeders for actuating said coin-deliverers, and means for moving said coin-deliverers out of the path of their actuating means, substantially as described.

10. A machine of the character described comprising coin-holders, coin-feeders, coin-deliverers movable angularly with respect to said coin-feeders, means carried by said coin-feeders for operating said coin-deliverers, and means for preventing the operation of one or more of said coin-deliverers, substantially as described.

11. A machine of the character described comprising coin-holders, coin-feeders, coin-deliverers movable angularly with respect to said coin-feeders, means carried by said coin-feeders for operating said coin-deliverers and means for moving one or more of said coin-deliverers out of the path of said operating means, substantially as described.

12. In a machine of the class described, the combination of a coin-holder, a movable coin-deliveror, a movable coin-feeder, said feeder and deliverer having coacting means whereby the latter may be operated by the former, a feeder-operator, coin-controlled means to connect said feeder-operator and said feeder, and means to prevent the operation of the coin-deliveror by the coin-feeder.

13. In a machine of the character described, the combination of a tilting coin-deliverer, a sliding coin-feeder to carry a coin thereto, and coacting means for tilting the deliverer after the coin has been carried thereto by the feeder.

14. In a machine of the character described, the combination of a tilting coin-deliverer, a sliding coin-feeder coacting therewith, and a cam-and-pin connection between said feeder and said deliverer for tilting said deliverer when the feeder is moved in one direction and restoring the same to its normal position when said feeder is moved in the opposite direction, substantially as described.

15. In a machine of the character described, the combination of a tilting coin-deliverer, a sliding coin-feeder coacting therewith, said feeder and deliverer having coacting means for operating the latter and means for preventing the operation of said deliverer, substantially as described.

16. The combination of a coin-holder, a sliding coin-feeder, a tilting coin-deliverer, fed and tilted by the coin-feeder, to deliver a coin, and means to prevent the tilting of the deliverer by the feeder.

17. In a machine of the character described, the combination of a coin-feeder, a movable element, a tilting coin-deliverer mounted upon said element to coact with said feeder, and a stop for limiting the tilting movement of said deliverer, substantially as described.

18. In a machine of the character described, the combination of a coin-feeder, a movable element, a tilting coin-deliverer mounted upon said element to coact with said feeder, means upon said feeder for actuating said deliverer and a key-lever for operating said element to move said deliverer out of the path of its operating means, substantially as described.

19. In a machine of the character described, the combination of a coin-holder, a coin-deliveror, a coin-feeder for feeding coins from said holder to said deliveror, a sliding feeder-operator and means for connecting and disconnecting said feeder-operator to and from said feeder, substantially as described.

20. In a machine of the character described, the combination of a coin-holder, a coin-deliveror, a coin-feeder for feeding coins from said holder to said deliveror, a sliding feeder-operator, means for moving said feeder-operator, and means for imparting the motion of said feeder-operator to said feeder, substantially as described.

21. In a machine of the character described, the combination of a coin-holder, a coin-deliverer, a coin-feeder for feeding coins from said holder to said deliverer, a feeder-operator, and a coin-controlled means for connecting said feeder and feeder-operator, substantially as described.

22. In a machine of the character described, the combination of a coin-deliverer, a feeder therefor, a feeder-operator, a swinging element for connecting said feeder and feeder-operator together, and coin-controlled means for operating said swinging element, said coin-controlled means coacting with the feeder-operator.

23. The combination of a coin-feeder mounted for sliding movement, a feeder-operator mounted for sliding movement, means to actuate the feeder-operator, a swinging element to connect said feeder and feeder-operator together for simultaneous movement, a spring to normally retain the swinging element in disengaged position with respect to the feeder and feeder-operator, and a check-actuated lever to engage the swinging element with the feeder and feeder-operator and cause said feeder and feeder-operator to move in unison.

24. In a machine of the character described, the combination of a sliding coin-feeder, provided with a slot, a sliding feeder-operator provided with a slot, a movable element adapted to enter said slots to lock said feeder and feeder-operator together, and means for operating said element, substantially as described.

25. In a machine of the character described, the combination of a coin-feeder, a feeder-operator, a coanector for said feeder and feeder-operator, a rotary element having a coin or check receiving pocket, a lever coacting with said element and adapted to actuate said connector, and a trip upon said lever adapted to be engaged by a coin or check in the pocket of said element, substantially as described.

26. In a machine of the character described, the combination of a coin-holder, a coin-conductor leading thereto, a rotary coin-receiving element, and a swinging coin-conducting element coacting with said rotary coin-receiving element and communicating with said coin-conductor, substantially as described.

27. In a machine of the character described, the combination of a coin-holder, a coin-conductor leading thereto, a coin-receiving disk formed with a coin-pocket in its periphery, a troughed arc-shaped coin-conducting element, coacting with said disk and said conductor, and a trip-roller in said troughed arc-shaped element, substantially as described.

28. In a machine of the character described, the combination of a suitable frame or casing formed with a coin-slot, a coin-guide upon the inner side of said frame or casing adjacent to said slot, a coin-receiving disk mounted adjacent to said guide and formed in its periphery with a coin-pocket, whereby a coin of a predetermined size will be retained in said pocket by said guide, and a coin of a smaller size than that designed to be inserted in said slot, will be permitted to fall out of said pocket, said slot preventing coins of larger denomination from being placed in said coin-pocket, substantially as described.

29. In a machine of the character described, the combination of a disk having a coin-pocket in its periphery, a troughed arc-shaped operating-lever coacting therewith, and a trip-roller journaled in said troughed lever and adapted to be engaged by a coin in the pocket of said disk, substantially as described.

30. In a machine of the character described, the combination of a coin-feeder, a feeder-operator therefor, a shaft, a disk upon said shaft formed with a cam-slot, a lever connected to said feeder-operator and pivoted intermediate its ends, a link connected to said lever and formed with a forked end to engage said shaft, and a stud upon said link to travel in said cam-slot, substantially as described.

31. In a machine of the character described, the combination of a sliding coin-feeder formed with a coin-pocket of less width than the diameter of said coin, and a tilting coin-deliverer adapted to pick said coin from said pocket, substantially as described

32. A change-making machine having a series of coin-deliverer controllers of inferior value, a series of operating-keys therefor, means to enable any desired number of the controllers to be simultaneously operated by an appropriate key, a substitute coin-deliverer controller of a value equal to that of the sum of the inferior-value-coin-deliverer controllers, and means to alternately put the inferior-value-coin-deliverer controller and the substitute coin-deliverer controller into operation.

33. A change-making machine having a series of coin-deliverer controllers of inferior value, operating-keys therefor, a substitute coin-deliverer controller of a value equal to that of the sum of the inferior-value-coin-deliverer controllers, a series of coin-deliverer controllers of superior value, two alternately-operative superior-value series of keys for said superior-value-coin-deliverer controllers, and means to put one of the superior-value series of keys and either the inferior-value series of keys or the substitute coin-deliverer controller out of operation.

34. A change-making machine having a series of coin-deliverer controllers of inferior value, a series of inferior-value operating-keys therefor, means to enable any desired number of the controllers to be simultaneously operated by an appropriate key, a substitute coin-deliverer controller of a value equal to that of the sum of the inferior-value-coin-deliverer controllers, a series of coin-deliverer controllers of superior value, two alternately-operative superior-value series of keys for said superior-value-coin-deliverer controllers, and means to put one of the superior-value series of keys and either the inferior-value series of keys or the substitute coin-deliverer controller out of operation.

35. In a machine of the character described, the combination of a suitable support, a crank-shaft mounted therein, a series of coin-receiving elements upon said shaft for coins of different denominations, a holder for coins of different denominations, conductors for directing the coins placed in said elements into said holder, deliverers for the coins in said holder, coin-feeders for said deliverers, operators for said feeders, drive connections between said shaft and said operators, coin-actuated means coacting with said coin-receiving elements for locking said feeders to said operators, and means to receive the coins discharged from said deliverers, substantially as described.

36. A change-making machine having two groups of purchase-keys, one for use when a certain value or multiples thereof are to be deducted from a coin deposited in the machine and the other for use when intermediate values are to be deducted, and means for preventing the use of more than one of said groups at the same time.

37. A change-making machine having two groups of purchase-keys, one for use when a certain value or multiples thereof are to be deducted from a coin deposited in the machine and the other for use when intermediate values are to be deducted and means for rendering one of said groups inoperative.

38. A change-making machine having two groups of purchase-keys, one for use when a certain value or multiples thereof are to be deducted from a coin deposited in the machine and the other for use when intermediate values are to be deducted and means for simultaneously throwing one of said groups into operation and the other out of operation.

39. A change-making machine having two groups of purchase-keys, one for use when a certain value or multiples thereof are to be deducted from a coin deposited in the machine and the other for use when intermediate values are to be deducted, and a swinging element for preventing the use of one or the other of said groups.

40. In a machine of the character described, the combination of a superior-coin-deliverer controller, a plurality of inferior-coin-deliverer controllers, a swinging element coacting with said superior-coin-deliverer controller, key-levers for operating one or more of said inferior-coin-deliverer controllers, and key-levers for operating said swinging element and a predetermined number of said inferior-coin-deliverer controllers, substantially as described.

41. In a machine of the character described, the combination of a dime-deliverer controller, a nickel-deliverer controller, five one-cent-deliverer controllers, and means for alternately moving said dime-deliverer controller or said nickel and one-cent deliverer controllers to an inoperative position, substantially as described.

42. In a machine of the character described, the combination of a dime-deliverer controller, a nickel-deliverer controller, five one-cent-deliverer controllers, and means for simultaneously moving said dime-deliverer controller into an operative position and said nickel and one-cent deliverer controllers to inoperative positions, substantially as described.

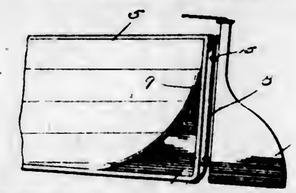
43. In a machine of the character described, the combination of a dime-deliverer controller, a nickel-deliverer controller, five one-cent-deliverer controllers, and cams for simultaneously moving said dime-deliverer controller into an operative position and said nickel and one-cent deliverer controllers to inoperative positions.

44. In a change-making machine the combination of a suitable frame, a swinging bracket mounted thereon, and a removable coin-holder slidably mounted upon said bracket, substantially as described.

812,161. **RUDDER.** GEORGE T. ARNOLD, Oshkosh, Wis., assignor of one-half to Harry W. Lewis, Oshkosh, Wis. Filed July 26, 1904. Serial No. 218,667.

Claim.—1. The combination with a boat, of a rod secured to the stern thereof and spaced therefrom and arranged for movement of its upper end toward and away from the stern, and a rudder having eyes, said rudder being disposed with its eyes in engagement with the rod.

2. The combination with a boat, of a rod secured at its lower end to the stern of the boat and spaced therefrom, said rod being arranged for movement of its upper end toward and away from the stern, a rudder, eyes carried by the rudder and removably engaged with the rod, and means for holding the upper end of the rod at the limit of its movement in the direction of the stern.

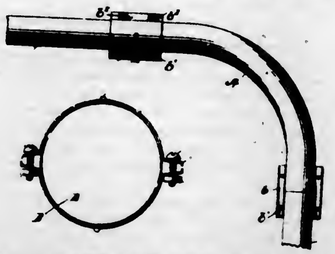


3. The combination with a boat, of a rod connected at one end with the boat for movement of its other end toward and away from the boat, a rudder having eyes in which the rod is engaged, and means for holding the rod against movement.

4. The combination with a boat, of a rod hinged at one end to the boat for movement toward and away from the latter, a rudder having eyes engaged with the rod, and means for holding the rod against movement away from the boat.

5. The combination with a boat, of a rod secured to the boat, and arranged for movement of one end toward and away from the boat, a rudder having eyes engaged with the rod, and means for holding the rod against movement laterally of the boat.

812,162. **PNEUMATIC TUBE FOR STORE SERVICE.** THOMAS BERRY, Indianapolis, Ind. Filed Dec. 18, 1905. Serial No. 292,330.



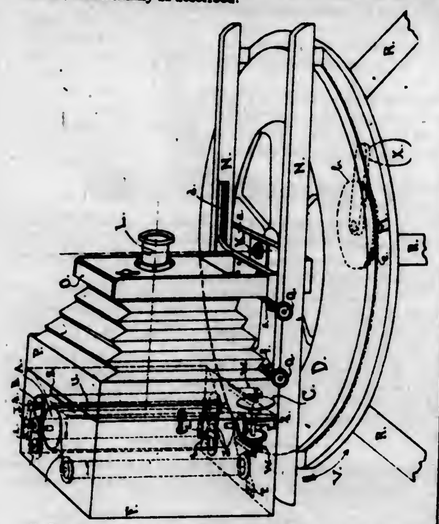
Claim.—1. A pneumatic tube for store service comprising a plurality of sections coupled together by a divided sleeve, a separate divided cylindrical section secured within said sleeve with its joint to one side of the joint in said sleeve, each edge of said sleeve having an outwardly-extending flange, which flanges extend toward each other at an angle and have their outer edges turned toward each other and adapted to meet to form a rib with a closed outer edge, and clamping-bolts extending through said flanges to draw them toward each other and clamp said sleeve upon said tube-sections, substantially as set forth.

2. In a pneumatic tube for store service, &c., the combination with two sections thereof, of a clamping-sleeve for securing them together comprising two parts, each part being substantially semicylindrical in form with outwardly-extending flanges on its edges, clamping-bolts extending through said flanges, and a second semicylindrical part secured within each part of said clamping-sleeve with one edge extending beyond the edge of said clamping-sleeve part and its other edge not extending to the edge of said sleeve part, whereby said internal sections when brought together form a complete cylinder with a smooth interior surface with joints to one side of the joints between said sleeve parts, substantially as set forth.

812,163. **PANORAMIC CAMERA.** JULIUS A. BAUM, San Francisco, Cal. Filed Aug. 9, 1904. Serial No. 219,126.

Claim.—1. In an apparatus of the character described, the combination of a camera-frame, a lens, means for rotating the frame about a vertical axis through the optical center of the lens, a film-support, mechanism for moving a film over said support in the direction opposite to its movement due to the rotation of the frame about said vertical axis, a revolving wheel carried on the camera-frame and operatively connected with said mechanism to move the film backward,

and an element with which said wheel engages to impart revolution to said wheel from the rotation of the camera-frame, the speed so imparted to said wheel varying directly as the distance from said vertical axis, substantially as described.



2. In an apparatus of the character described, the combination of a camera-frame, a lens, means for rotating said frame about a vertical axis through the optical center of the lens, a film-support, means for moving a film over said support, in the direction opposite to its movement due to the rotation of the frame about said vertical axis, a wheel for operating said moving film, and an element having a surface with which said wheel is in frictional contact, said surface being one of revolution about a point in said vertical axis, whereby the velocity of said wheel varies as its distance from the vertical axis, substantially as described.

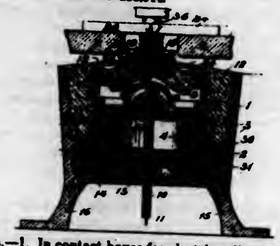
3. In an apparatus of the character described, the combination of a camera-frame, a lens, means for rotating the frame about a vertical axis through the optical center of the lens, a film-support, means for moving a film in the direction opposite to its motion due to the rotation of the frame about said vertical axis, said means comprising a vertical shaft, a horizontal shaft, bevel-gears on said shafts meshing with each other, a friction-disk on said horizontal shaft, and an element having a surface of revolution about a point in said vertical axis as center, with which element the friction-disk has frictional engagement to rotate the disk by the revolution of the camera-frame, substantially as described.

4. In an apparatus of the character described, the combination of a camera-frame, a lens, means for rotating the frame about a vertical axis through the optical center of the lens, a film-holder carried on said frame, supply and winding rollers in said film-holder, a roller over which said film is passed, means for driving said latter roller, including a horizontal shaft, bevel-gears on said shaft and on the shaft of the roller, a disk on said horizontal shaft, and an element having a surface of revolution about a point in said vertical axis as center with which said disk has engagement, to revolve the disk as the camera-frame rotates, substantially as described.

5. In an apparatus of the character described, the combination of a camera-frame, a lens means for rotating the frame about a vertical axis through the optical center of the lens, a film-holder, supply and winding spools therein, a roller over which said film passes, a pressure-roller, resilient means for pressing said pressure-roller against said first roller, and means operated by the revolution of the camera-frame for revolving said first roller in a direction so that the film travels thereover in the direction opposite to its motion due to the camera-frame as a whole, substantially as described

6. In an apparatus of the character described, the combination of a camera-frame having an aperture, a lens, means for rotating said frame about a vertical axis through the optical center of the lens, a film-holder carried on the camera-frame, a roller in said film-holder over which the film passes and whose axis is in the plane of the middle of the aperture and lens, means for revolving the roller in a direction so that the film passes thereover in a direction opposite to that due to the motion of the camera-frame, supply and winding spools, and a braking device for the supply-spool whereby the film is maintained tight over the roller, substantially as described.

812,164. CONTACT-BOX FOR ELECTRIC-RAILWAY SYSTEMS. GEORGE L. CAMPBELL, Williamsport, Pa., assignor to Railways Surface Contact Supplies Company, a Corporation of Delaware. Filed Dec. 20, 1904. Serial No. 238,014.



Claim.—1. In contact-boxes for electric-railway systems, a metallic casing formed with internal lugs having inclined lower faces adjacent the bottom of said casing, a box within said casing and provided with lugs having inclined upper faces coöperating with the lugs on said casing, an insulating supporting member between said box and casing, insulating wedging members between the coöperating lugs on said box and casing, the spaces between said box and casing being filled with insulating-cement, said box being provided with a projecting conducting-cover of non-magnetic material, magnetic cores in said cover and projecting within said box, an insulated contact within said box to be connected with a feed-wire, a coöperating electrical contact on said cover and a hollow spherical closer of magnetic material normally out of contact with said cover and adapted to be magnetically actuated by said cores under the influence of the car-magnet to close electrical connection between said contacts.

2. In contact-boxes for electric-railway systems, a metallic casing formed with internal lugs, a box within the casing and provided with lugs coöperating with the lugs on said casing, wedging insulating members between said box and casing, the spaces between said box and casing being filled with an insulating sealing medium, said box being provided with a conducting-cover of non-magnetic material, magnetic cores in said cover, an insulated contact within said box to be connected with a feed-wire, a coöperating electrical contact on said cover, and a hollow hemispherical closer of magnetic material normally resting on an insulated support within said box and adapted to be magnetically actuated by said cores under the influence of the car-magnet to close electrical connection between said contacts.

3. In contact-boxes for electric-railway systems, a casing formed with internal lugs having inclined faces adjacent the bottom of said casing, a box within said casing provided with lugs having inclined upper faces coöperating with the lugs on said casing, insulating members, including wedging members engaging said lugs between said box and said casing, the spaces between said box and casing being filled with an insulating sealing medium, said box being provided with a projecting conducting-cover and means to electrically connect said cover with a feed-wire.

4. In contact-boxes for electric-railway systems, a casing formed with internal lugs, a box within said casing and separated therefrom by insulating members, means on said box coöperating with said lugs to hold said box and casing in relative position and insulate them from each other, the spaces between said box and casing being filled with an insulating sealing medium, said box being provided with a cover of conducting material and means to electrically connect said cover with a feed-wire.

5. In contact-boxes for electric-railway systems, a casing formed with internal lugs, a box within said casing and insulated therefrom, said box having means coöperating with said lugs to hold said box and casing in proper relative position and the spaces between said box and casing being filled with an insulating viscous sealing medium.

6. In contact-boxes for electric-railway systems, a casing formed with internal lugs having inclined lower faces, a box within said casing and provided with lugs having inclined upper faces coöperating with the lugs on said casing and insulating members comprising wedging members between said lugs to separate said box and said casing.

7. In contact-boxes for electric-railway systems, a box having a conducting non-magnetic cover, magnetic cores in said cover, an insulating-support within said box, a contact on said support to be connected with a feed-wire, a coöperating inclined laterally-disposed contact on said cover, a hollow closer-shell loosely fitting over a guide formed on said support and adapted to make electrical connection between said contacts when drawn upward by said cores under the influence of a car-magnet.

812,165. TIRE. JOHN L. CONNABLE, Chattanooga, Tenn.; Caroline Augusta Connable, executrix of said John L. Connable, deceased, assignor of one-half to Frank L. Connable, Wilmington, Del. Filed Apr. 3, 1901. Serial No. 54,167.

Claim.—1. In a rubber tire in combination with a rim, retaining means, a passage or passages in the tire for said retaining means, a rigid bearing-plate supported solely by its bearing in the rim and engagement with the tire and having a rigid bearing on the rim and provided with a thin, sharp projecting portion having its bearing edge extending into said passage or passages whereby said retaining means are suspended independently of the rubber tire and without pressure on the walls of said passage or passages, substantially as described

2. In a rubber tire in combination with a rim, retaining means, a rigid bearing-plate having a rigid bearing on the rim and provided with a bridge or lug projecting at an angle thereto having an edge over which said retaining means are drawn and stretched, said edge formed with embracing portions adapted to receive and support said retaining means and hold the same out of contact with the resilient portion of the tire, said plate supported solely by said bearing on the rim and the projection of the bridge or lug into the tube, substantially as described.

3. In a rubber tire, in combination with a rim, retaining means for the tire, a rigid bearing-plate provided with a projecting bridge or lug adapted to support said retaining means and a thin non-elastic section of the tire between said plate and said rim whereby said plate will be given a rigid bearing on said rim but will be retained within said tire and protected from the weather said plate supported solely by its bearing from and on the rim and engagement of said bridge with the tire, substantially as described.

4. In a rubber tire, in combination with retaining means, a series of separated rigid bearing-plates independent of the rim and provided with base portions having a rigid bearing thereon said plates embedded in the tire, and having projecting bridges rising from said base portions over which said retaining means are stretched and bent, and held independently of the rubber, substantially as described.

5. In a rubber tire having a retaining-wire, a bearing-plate for said retaining-wire having all of its edges flanged, substantially as described.

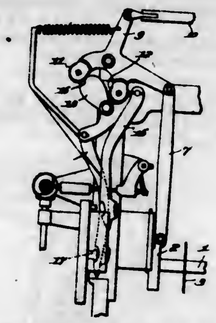
6. In a rubber tire, a retaining-wire, a bearing-plate for said retaining-wire having its end edges rolled or bent up at an angle to the body portion of the plate and forming rounded edges and holding-flanges, substantially as described.

7. In a rubber tire, retaining means, a bearing-plate having side flanges extending at an angle from the plate and on which the retaining means are supported, and end flanges forming with the side flanges a rubber-gripping channel in the plate, substantially as described.

8. In a rubber tire, a retaining-wire, a bearing-plate having diagonally opposite supporting-bridges, and a strengthening-rib extending longitudinally of the plate, substantially as described.

812,166. HARNESS-MOTION FOR LOOMS. HENRY CYR, Biddeford, Me., assignor to Draper Company, Hopedale, Mass., a Corporation of Maine. Filed Nov. 2, 1905. Serial No. 285,282.

Claim.—1. A harness-motion for looms having, in combination, a heddle-frame, a rocking lever operatively connected therewith, a roll on said lever, a cam-lever to coöperate with said roll to depress the heddle-frame, said cam-lever having a locking-rest to engage the roll when the heddle-frame is in lowered position, and independent means acting at such times through the rocking lever to maintain the roll in the locking-rest.



2. A harness-motion for looms having, in combination, a heddle-frame, a rocking member operatively connected therewith and provided with a follower, a cam-lever to coöperate with said follower to depress the heddle-frame, said cam-lever having a locking-rest to engage the follower when the heddle-frame is in lowered position, and means acting at such time to maintain the follower and locking-rest in coöperation, to prevent accidental movement of the cam-lever.

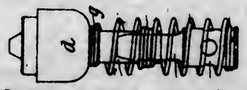
3. A harness-motion for looms having, in combination, a heddle-frame, a rocking member operatively connected therewith and provided with a follower, a cam-lever to coöperate with said follower to depress the heddle-frame, said cam-lever having a locking-rest to engage the follower when the heddle-frame is in lowered position, and a spring under tension at such time acting to maintain the follower and locking-rest in coöperation.

4. A harness-motion for looms, having in combination, a heddle-frame, a rocking member operatively connected therewith and provided with a follower, a cam-lever to coöperate with said follower to depress the heddle-frame, said cam-lever having a locking-rest to engage the follower when the heddle-frame is in lowered position, and a spring fixed at one end and connected at its other end with the rocking lever and stretched by movement thereof to lower the heddle-frame, the tension of the spring acting when the heddle-frame is in lowered position to press the follower into the locking-rest and thereby prevent disengagement and improper movement of the cam-lever.

5. A harness-motion for looms having, in combination, a heddle-frame, means to reciprocate it, including a cam-lever having a locking-rest, and a follower to engage the locking-rest when the heddle-frame is in lowered position, and means rendered operative at such time to maintain the follower in coöperation with the locking-rest.

6. A harness-motion for looms having, in combination, a heddle-frame, means to reciprocate it, means to lock the heddle-frame in raised or lowered position, and a safety device acting only when the heddle-frame is in lowered position to insure the operation of the locking means at such time.

812,167. ANTIVIBRATOR BURNER FOR INCANDESCENT GAS-LIGHTS. CHARLES P. REMANE, Manchester, England. Filed Jan. 27, 1905. Serial No. 242,998.



Claim.—1. In a burner for incandescent gas-lights the combination of a mixing-chamber having a mixing-tube extending upward the upper end of said tube being tapered, a burner-head having a socket extending downward and surrounding said mixing-tube and of larger internal diameter than the external diameter of the mixing-tube and a helical spring loosely surrounding said mixing-chamber and socket and constricted at each end so as to embrace the mixing-chamber at its base and to grip the socket underneath said burner-head.

2. In a burner for incandescent gas-light the combination of a mixing-chamber having a mixing-tube extending upward, a burner-head having a socket extending downward and surrounding said mixing-tube, said socket having an internal diameter larger than the

external diameter of said mixing-tube, and a helical spring loosely surrounding said mixing-chamber and socket, and constricted at both ends and at an intervening point in such a manner as to embrace the said mixing-chamber and socket at each end and at the said intervening point, substantially as described.

3. In a burner for incandescent gas-light the combination of a mixing-chamber having a mixing-tube extending upward, a burner-head having a socket extending downward and surrounding said mixing-tube, said socket having an internal diameter larger than the external diameter of said mixing-tube, and a helical spring loosely surrounding said mixing-chamber and socket, and constricted at both ends and at an intervening point in such a manner as to embrace the said mixing-chamber and socket at each end and at the said intervening point, and a perforated shade for said burner, substantially as described.

4. In a burner for incandescent gas-light the combination of a mixing-chamber having a mixing-tube extending upward, a burner-head having a socket extending downward and surrounding said mixing-tube, said socket having an internal diameter larger than the external diameter of said mixing-tube, and a helical spring loosely surrounding said mixing-chamber and socket, and constricted at both ends and at an intervening point in such a manner as to embrace the said mixing-chamber and socket at each end and at the said intervening point, and a perforated shade for said burner, said shade being arranged to cover a portion of the window to which the trap is attached.

with a surface-level in proximity to, but not in contact with, the drum-surface under the magnet-pole, an inlet for the ore whereby it may

ing the first funnel and having a discharge-tube adjustable by means of a valve, a third funnel

external diameter of said mixing-tube, and a helical spring loosely surrounding said mixing-chamber and socket, and constricted at both ends said at an intervening point in such a manner as to embrace the said mixing-chamber at its lower end and to grip said socket underneath the burner-head at its upper end and to embrace the socket at the intervening point without gripping it.

812,168. STOCKING. JOHN H. FREEMAN, New York, N. Y., assignor of one-half to Thomas A. O'Callaghan, Hoboken, N. J. Filed Oct. 9, 1903. Serial No. 176,948.

Claim.—1. A stocking having secured thereto an attaching portion for a garter-clasp provided with upwardly-divergent sides to distribute the strain upon the stocking material.

2. A stocking having at its upper end attaching portions for garter-clasps, said attaching portions diverging from their lower central points toward their upper edges to distribute the strain upon the stocking material.

3. A stocking having attaching portions imposed thereon adjacent to its upper end, and having inclined sides, secured to said stocking, and a horizontal upper edge free therefrom, substantially as specified.

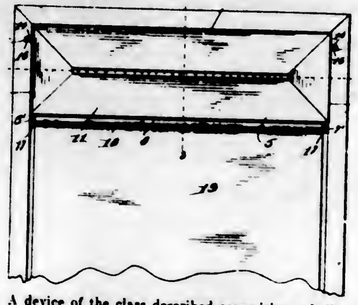
4. A stocking having a plurality of attaching portions imposed thereon having inclined sides secured along the edges of said inclined sides to said stocking, and horizontal upper edges arranged parallel with the upper edge of the stocking, substantially as specified.

5. A stocking having a plurality of attaching portions of triangular outline imposed thereon and incorporated into the same, and united at their inclined edges with said stocking, and having their bases on a line with the upper edge of the stocking but free therefrom, substantially as specified.

6. The combination in a hose of a leg portion having a top edge or open end in a plane transverse to the general axial line of the limb of the wearer when the hose is in use, of a pair of attaching devices carried thereby and having lines of securement on the leg adjacent to and below such top and diverging thereto ward and ending in free edges at the edge of the said leg portion and adapted when engaged by a fastener and under the influence of a supporter to circumferentially constrict the said top edge of the leg portion upon the leg of the wearer in said plane, substantially as specified.

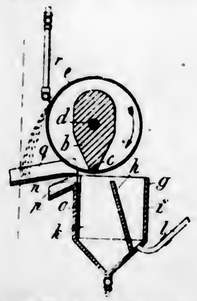
812,169. FLY-TRAP. WILLIAM H. GRASSER, Leland, Idaho, assignor of one-third to Augusta Grasser and one-third to Jasper P. Grasser, Orofino, Idaho. Filed Apr. 19, 1905. Serial No. 256,630.

Claim.—1. The combination with a window of a fly-trap removably secured thereto in position to cover a portion of the window said trap comprising a body portion having closed ends, a foraminous rear wall, an inwardly-directed tapered chute in its wall which lies away from the window said chute having translucent walls, and a window-shade secured to the body portion and extending therebelow said shade being arranged to cover a portion of the window to which the trap is attached.



2. A device of the class described comprising a hollow body portion including ends having downwardly-extending portions, said body portion having a foraminous rear wall arranged for the passage of light into the body portion, an inwardly-directed chute carried by the body portion at its forward side, said chute having translucent walls and having an ingress-passage formed therein, attaching devices carried by the ends of the body portion for supporting the same, and shade-supporting devices secured to the inner surfaces of the downwardly-extending portions of the ends.

812,170. APPARATUS FOR MAGNETIC SEPARATION OF IRON ORE. GUSTAF GRÖNDAL, Djursholm, Sweden. Filed Nov. 12, 1903. Serial No. 180,904.



Claim.—1. Apparatus for magnetically separating ores, consisting of a magnet, a moving surface under the magnet-pole, a compartment having an overflow to maintain a body of liquid with a surface-level in proximity to but not in contact with said moving surface under the magnet-pole, an inlet for the ore whereby it may float suspended in the said liquid, and an outlet for the non-magnetic material from the lower part of the compartment, and a channel to carry off the magnetic material which has been drawn out of the water.

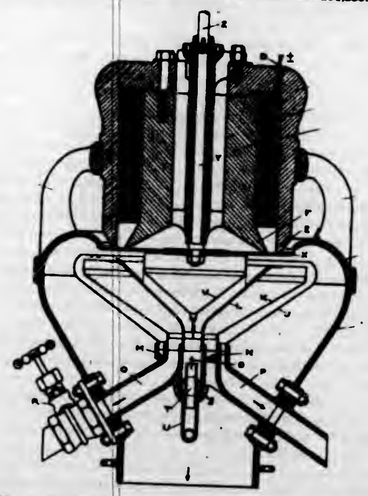
2. Apparatus for magnetically separating ores, consisting of a magnet, a moving surface under the magnet-pole, a compartment having an overflow to maintain a body of liquid with a surface-level in proximity to but not in contact with said moving surface under the magnet-pole and at the same time to carry off the less magnetic particles drawn to the surface of but not out of the water, an inlet for the ore whereby it may float suspended in the said liquid, an outlet for the non-magnetic material from the lower part of the compartment and a channel to carry off the magnetic material drawn out of the water.

3. Apparatus for magnetically separating ores, consisting of a magnet, a moving surface under the magnet-pole, two compartments, the first adapted to receive the ore suspended in water and to overflow the same into the second compartment, the two adapted to maintain the body of liquid with a surface-level in proximity to, but out of contact with, said moving surface under the magnet-pole, an outlet for the non-magnetic material from the lower part of the second compartment, and a channel to carry off the magnetic material which has been drawn out of the water.

4. Apparatus for magnetically separating ores, consisting of a magnet, a revolving lamellated drum having the magnet-pole within it, a compartment having an overflow to maintain a body of liquid with a surface-level in proximity to, but not in contact with, the drum-surface under the magnet-pole, an inlet for the ore whereby it may float suspended in the said liquid and an outlet for the non-magnetic material from the lower part of the compartment and a channel to carry off the magnetic material which has been drawn out of the water.

5. An apparatus for magnetically separating iron ores, comprising a stationary electromagnet, having a pole-piece formed with an elongated edge, a rotating hollow drum of a magnetically indifferent material provided with iron lamellæ in its mantle surrounding the pole-piece, and means for passing the current containing the suspended material to be separated past, beneath and out of contact with the drum in such a manner that the direction of motion is at right angles against the edge of the pole-piece of the magnet, and the same as the direction of motion of the drum whose mantle moves between the edge of the pole-piece and the current of water, said means consisting of a vessel located under the drum, a partition dividing it into two compartments lying side by side, the one compartment being provided at the bottom with a supply-pipe for the suspended material, and the other compartment being provided at the bottom with a discharge-conduit for the non-magnetic part of the material, and at the top with an overflow-discharge for the less magnetic part of the material.

812,171. MAGNETIC ORE-SEPARATOR. GUSTAF GRÖNDAL, Djursholm, Sweden. Filed Nov. 3, 1904. Serial No. 231,238.



Claim.—1. A magnetic separator for ore suspended in water, comprising an electromagnet with its pole-pieces directed downward, a horizontal rotary disk beneath said poles and means for feeding ore suspended in water upward from below toward the disk and horizontally in close proximity thereto, but out of contact therewith, as and for the purpose set forth.

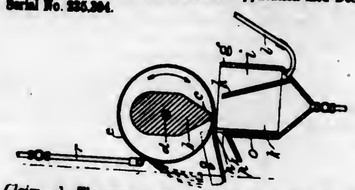
2. A magnetic separator for ore suspended in water, comprising an annular electromagnet with its pole-pieces directed downward, a rotary disk beneath said pole-pieces and beneath said disk two annular vessels, means for supplying ore suspended in water upward through one of said vessels and over the edge to the other, and in close proximity to, but out of contact with, the rotary disk.

3. A magnetic separator for ore suspended in water, comprising an electromagnet with its pole-pieces directed downward, a rotary disk beneath said pole-pieces, and beneath said disk two annular vessels, means for supplying ore suspended in water upward through one of said vessels and to the other, with an outer vessel to receive and collect the rich ore drawn out of the water and thrown off the disk by centrifugal force.

4. A magnetic ore-separator comprising an upright cylindrical electromagnet having its pole pieces directed downward in the shape of concentric rings, a rapidly-rotating disk beneath the pole-pieces, and beneath the said disk a funnel provided with a conical disperser inserted in it and with tubes for the suspended material and for water, opening into the lower part of the funnel, another funnel surrounding the first funnel and having a discharge-tube adjustable by means of a valve, a third funnel surrounding the second funnel having a discharge-tube, and a collecting vessel surrounding the circumference of the disk.

5. A magnetic separator for ore suspended in water, comprising an electromagnet, a moving surface beneath the pole-piece, and above the water-level a vessel for receiving ore suspended in water below said moving surface, an inlet to the lower part of said vessel and a water-jet tube in the said inlet to press the water and ore upward.

812,172. MAGNETIC SEPARATION OF IRON ORE. GUSTAF GRÖNDAL, Djursholm, Sweden. Original application filed Nov. 12, 1903. Serial No. 180,904. Divided and this application filed Dec. 3, 1904. Serial No. 235,304.

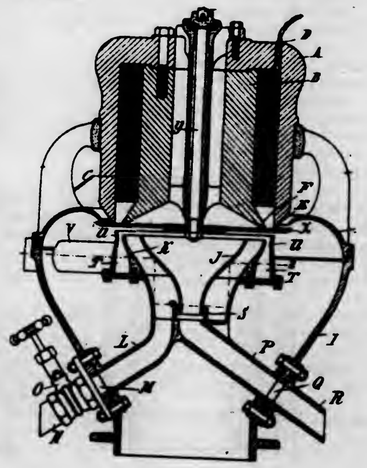


Claim.—1. The process of separating pulverized ore, consisting in suspending said ore in a body of liquid, maintaining the surface-level of this liquid substantially horizontal under a moving surface in proximity to but free from contact with the surface of the liquid, magnetically lifting the more magnetic particles out of the water to said moving surface, removing the particles from the latter at another point, and withdrawing the non-magnetic material at the bottom of the body of liquid.

2. The process of separating pulverized ore, consisting in suspending said ore in a body of liquid, maintaining the horizontal surface-level of this liquid under a moving surface in proximity to but free from contact with the surface of the liquid by maintaining a surface overflow, magnetically lifting the more magnetic particles out of the liquid into a layer on the said moving surface, gathering the layer of particles which have been lifted out of the water, and withdrawing the non-magnetic material at the bottom of the body of the liquid.

3. The process of separating pulverized ore, consisting in leading a stream of liquid carrying the ore horizontally below in proximity to but free from contact with a moving surface, magnetically pulling the most magnetic particles of ore up out of the liquid into a layer on said moving surface and at the same time gathering less magnetic particles of ore in the liquid near its surface and leading the same away and letting the dead ore sink down in the liquid and flow away.

812,173. MAGNETIC ORE-SEPARATOR. GUSTAF GRÖNDAL, Djursholm, Sweden. Original application filed Nov. 3, 1904. Serial No. 231,238. Divided and this application filed Apr. 7, 1905. Serial No. 254,296.

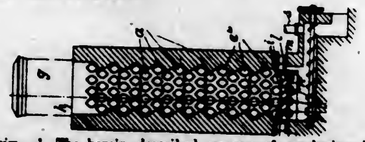


Claim.—1. A magnetic separator for powdered ore suspended in water, comprising an upright cylindrical electromagnet having its pole-pieces directed downward in the shape of concentric rings, beneath said pole-pieces a rapidly-rotating disk mounted on a vertical shaft and beneath said disk two annular vessels concentric to each other, an inlet for the fluid to the outer vessel and an adjustable discharge at the bottom of the inner vessel, the space inside said inner annular vessel being provided with an outlet for the fluid.

2. A magnetic separator for powdered ore suspended in water, comprising an upright cylindrical electromagnet having its pole-pieces directed downward in the shape of concentric rings, beneath said pole-pieces a rapidly-rotating disk mounted on a vertical shaft and beneath said disk two annular vessels concentric to each other, an inlet for the fluid to the outer vessel and an adjustable discharge at the bottom of the inner vessel, the space inside said inner annular vessel being provided with an outlet for the fluid, and a collecting vessel surrounding the circumference of the disk.

812,174. METHOD OF MANUFACTURING IRON SPONGE.

GUSTAF GRÖNDAL, Djursholm, Sweden. Original application filed Mar. 31, 1905. Serial No. 253,441. Divided and this application filed Apr. 4, 1905. Serial No. 253,876.



Claim.—1. The herein-described process of producing iron sponge, consisting in continually feeding the iron ore and carbon mixture through a furnace, and feeding a mixture of combustible gas and air divided into a number of streams repeatedly through the mixture in said furnace to reduce said mixture to iron sponge.

2. The herein-described process of producing iron sponge, consisting in continually feeding the iron ore and carbon mixture through a furnace, and feeding a mixture of combustible gas and air divided into a number of streams repeatedly through the mixture in said furnace to reduce said mixture to iron sponge, and feeding one of the components of said gas mixture divided into a number of streams repeatedly through the iron sponge produced.

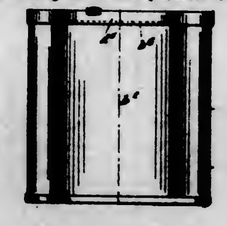
3. The herein-described process of producing iron sponge, consisting in continually feeding the iron ore and carbon mixture through a furnace, feeding a mixture of combustible gas and air divided into a number of streams repeatedly through the mixture in said furnace to reduce said mixture to iron sponge, feeding one of the components of said gas mixture divided into a number of streams repeatedly through the iron sponge produced, and carrying away the gases evolved from the mixture of iron ore and carbon during the reducing operation from the spot where they are generated.

4. The herein-described process of producing iron sponge, consisting in continually feeding the iron ore and carbon mixture through a furnace, and feeding a mixture of combustible gas and air divided into a number of streams repeatedly through the mixture in said furnace to reduce said mixture to iron sponge, and admitting a cooling agent for cooling the iron sponge.

5. The herein-described process of producing iron sponge, consisting in continually feeding the iron ore and carbon mixture through a furnace, and feeding a mixture of combustible gas and air divided into a number of streams repeatedly through the mixture in said furnace to reduce said mixture to iron sponge, and admitting a cooling agent for cooling the iron sponge, without coming into physical contact therewith.

812,175. SHEET-METAL POCKET-BOX.

ISAAC J. MARQUIS, Richmond, Va., assignor to R. A. Patterson Tobacco Co., Richmond, Va., a Corporation of Virginia. Filed July 3, 1905. Serial No. 268,079.



Claim.—1. The sheet-metal pocket-box herein shown and described, and comprising a curved or reniform bottom head, a curved or reniform body secured at its lower end to said bottom head and having an inwardly-curved or concave front wall and an outwardly-curved or convex back wall, and rounded side walls uniting said front and back walls, said outwardly-curved or convex back wall having at the upper end thereof an integral hinge-lip and a recess to receive the hinge-lips of the cover-flange, and said concave or inwardly-curved front wall having a strengthening-rib near the upper end thereof, and a curved or reniform hinged cover having an integral flange surrounding and snugly fitting the upper end of the box-body to hold the cover closed, the back convex curved portion of said cover-flange having an integral hinge-lip and being inclined or cut away to accommodate the convex or outwardly-curved back wall of the body and permit the hinged cover to open, the concave front wall of the body being free to spring inward under external pressure thereon and thus contract or loosen the body within the surrounding cover-flange to facilitate the opening of the hinged cover, substantially as specified.

2. A sheet-metal pocket-box having a reniform body with a convex back wall and concave front wall, and a hinged cover having a concave front flange and convex back flange hinged to the convex back wall of the body, said hinged convex portion of the cover-flange being inclined or cut away to permit the cover to open, the flange of the cover surrounding and snugly fitting the upper end of the body to hold the cover closed, and the concave front wall of the body being free to spring inward and thus contract or loosen the upper end of the body within the cover-flange to facilitate the opening of the hinged cover, substantially as specified.

3. In a sheet-metal pocket-box, the combination with a curved or reniform body, having a convex back wall and concave front wall, of a hinged cover having a flange concave at its front portion and convex at its rear portion, the flange of the cover surrounding and snugly fitting the upper end of the body to hold the cover closed, and the concave front wall of the body being free to spring inward and thus contract or loosen the upper end of the body within the cover-flange to facilitate the opening of the hinged cover, substantially as specified.

4. In a sheet-metal pocket-box, the combination with a curved or reniform body, having a convex back wall and concave front wall, of a hinged cover having a flange concave at its front portion and convex at its rear portion, the convex wall of the body having an integral hinge-lip at the upper end thereof, and the convex portion of the cover-flange having integral hinge-lips for pivotally connecting the same to the body of the box, the flange of the cover surrounding and snugly fitting the upper end of the body to hold the cover closed, and the concave front wall of the body being free to spring inward and thus contract or loosen the upper end of the body within the cover-flange to facilitate the opening of the hinged cover, substantially as specified.

5. In a sheet-metal pocket-box, the combination with a curved or reniform body, having a convex back wall and concave front wall, of a hinged cover having a flange concave at its front portion and convex at its rear portion, the convex wall of the body having an integral hinge-lip at the upper end thereof, and the convex portion of the cover-flange having integral hinge-lips for pivotally connecting the same to the body of the box, said convex portion of the cover-flange being inclined or cut away to accommodate the convex curvature of the back wall of the body, the flange of the cover surrounding and snugly fitting the upper end of the body to hold the cover closed, and the concave front wall of the body being free to spring inward and thus contract or loosen the upper end of the body within the cover-flange to facilitate the opening of the hinged cover, substantially as specified.

6. In a sheet-metal pocket-box, the combination with a curved or reniform body, having a convex back wall and concave front wall, of a hinged cover having a flange concave at its front portion and convex at its rear portion, the convex wall of the body having an integral hinge-lip at the upper end thereof, and the convex portion of the cover-flange having integral hinge-lips for pivotally connecting the same to the body of the box, said convex portion of the cover-flange being inclined or cut away to accommodate the convex curvature of the back wall of the body, the concave front wall of the body being provided with a strengthening-rib at the upper end thereof, the flange of the cover surrounding and snugly fitting the upper end of the body to hold the cover closed, and the concave front wall of the body being free to spring inward and thus contract or loosen the upper end of the body within the cover-flange to facilitate the opening of the hinged cover, substantially as specified.

7. In a sheet-metal box, the combination with a curved or reniform body composed of tin-plate or other flexible elastic sheet metal and having a convex back wall and concave front wall, of a hinged cover having a flange concave at its front portion and convex at its back portion, and surrounding and snugly engaging the upper end of the body to hold the cover closed, the inward spring of the concave front wall of the body under pressure serving to contract or loosen the body within the cover-flange and permitting the hinged cover to swing open, substantially as specified.

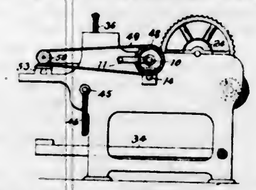
8. In a sheet-metal pocket-box, the combination with a reniform body of tin-plate having a concave front wall and convex back wall, of a hinged cover having a flange concave at its front portion and convex at its rear portion and surrounding and engaging the upper end of the body, the concave front wall of the tin-plate body being free to spring inward under external pressure to contract or loosen the upper end of the body within the cover-flange, substantially as specified.

9. In a sheet-metal pocket-box, the combination with a curved or reniform body composed of flexible spring sheet metal and having a concave front wall, of a cover having a flange surrounding and engaging the upper end of the body, the cover-flange being concave at its front portion, the inward spring of the concave front wall of the body serving to contract or loosen the body within the cover-flange to facilitate the opening of the cover, substantially as specified.

REISSUES.

12,445. MACHINE FOR TRIMMING AND APPLYING SHADE GOODS.

EPHRAIM O. ENGBERG, Salt Lake City, Utah, assignor to John Beecher Patton, Kent, Ohio. Filed July 22, 1905. Serial No. 270,876. Original No. 754,750, dated Mar. 15, 1904.



Claim.—1. In a machine for making window-shades, the combination with means for holding a web of shade material, of shade-roller-holding means, means for rotating the shade-roller-holding means to wind the material on the roller, means for trimming the edges of the material lengthwise thereof, means for cutting the material transversely, together with mechanism for creasing the material transversely thereof for forming the loop for the shade-slat and arranged in advance of the trimming means.

2. In a machine for making window-shades, the combination with means for holding a web of shade material, of shade-roller-holding means, means for rotating the shade-roller-holding means, a feeding device for the material forcing the same toward the shade-roller-holding means, knives for cutting the material lengthwise thereof, means for cutting the material transversely, together with devices for creasing the material transversely thereof for forming a loop for the shade-slat.

3. In a machine for making window-shades, the combination with means for holding a roll of shade material, of shade-roller-holding means, means for rotating the shade-roller-holding means, knives for cutting the material lengthwise thereof, feed-rolls located between the roll of material-holding means and said knives, means for cutting the material transversely, together with movable folding-blades creasing the material at distinct points for forming the shade-slat loop.

4. In a machine for making window-shades, the combination with means for holding a web of shade material, of shade-roller-holding means adapted to removably hold a shade-roller, feed-rolls for forcing the material toward the shade-roller-holding means, together with mechanism for creasing the material transversely thereof for forming a loop for the shade-slat.

5. In a machine for making window-shades, the combination with means for holding shade material, of shade-roller-holding means, means for rotating the shade-roller-holding means, knives for cutting the material lengthwise, folding means acting on the material and folding the same for the shade-slat, and a feeding device for forcing the material toward the folding means.

6. In a machine for making window-shades, the combination with means for holding a web of shade material, means for supporting a shade-roller to wind the material thereon, creasing devices for creasing the material transversely thereof at two distinct points for the shade-slat hem or loop, and means whereby the distance between the folds may be increased or diminished to make different sizes of loops for different sizes of shade-slats.

7. In a machine for making window-shades, the combination with means for holding shade material, of movable folding-blades forming distinct folds in the material to make the shade-slat loop or hem, and means whereby the distance between the folds may be increased or diminished to make different sizes of loops for different sizes of shade-slats.

8. In a machine for making window-shades, the combination with a frame and means for holding shade material, of means for winding the material on a shade-roller, trimming devices for trimming the edges of the material, mechanism for folding and creasing the material transversely thereof to form the loop for the shade-slat having two bends and an inturned end, together with means by which the material may be cut transversely.

9. In a machine for making window-shades, the combination with means for holding a web of shade material, of shade-roller-holding means adapted to removably hold a shade-roller, means for rotating the shade-roller-holding means for winding the material on the roller, together with mechanism for folding and creasing the material transversely thereof for forming a loop for the shade-slat.

10. In a machine of the character described, the combination with means for holding shade material, of means for rotating a shade-roller to wind the material thereon, together with folding means acting on the material and forming the loop for the shade-slat.

11. In a machine of the character described, the combination with means for holding a web of shade material, of folding and creasing devices adapted to fold and crease the material for forming the loop for the shade-slat, means for cutting the material lengthwise thereof, tension devices, together with means for cutting the material transversely thereof after the material has been creased.

12. In a machine of the character described, the combination with means for holding shade material, of two movable folding devices and independent creasing means having movable members for folding and creasing the material transversely thereof and forming the loop for the shade-slat, tension devices for the material, together with means for cutting the material transversely thereof.

13. In a machine of the character described, the combination with means for holding a web of shade material, means for removably holding a shade-roller, means for rotating the shade-roller-holding means to wind the material on the roller, together with mechanism for acting on the material transversely thereof and forming a loop having two bends adapted to hold the shade-slat.

14. In a machine for making window-shades, the combination with means for holding a web of shade material, of means for rotating a shade-roller to wind the material thereon, and creasing means for creasing the material transversely thereof and forming a loop having two bends and an inturned end extending within the loop.

15. In a machine for making window-shades, the combination with a frame and means for holding shade material, of means for operating on a shade-roller to wind the material thereon, means for cutting the material transversely, together with means for forming a shade-slat loop or socket at the point where the material is cut transversely.

16. In a machine of the character described, the combination with a frame, of means for holding shade material on the frame, means for rotating a shade-roller for winding the material thereon, together with means having movable members clamping the material between them and forming a shade-slat loop or socket in which one end is bent inward within the loop.

17. In a machine for making window-shades, the combination with means for holding shade material, of means for cutting the material transversely, together with two movable folding devices, and independent movable creasing devices acting on the material after it is folded means adjacent to the transverse cutting means for forming a shade-slat loop or socket having two bends with an inturned end adapted to lie close to the body of the material and within the loop.

18. In a machine for making window-shades, the combination with means for holding shade material, of independent holding devices, an independent movable creasing devices acting on the material after it has been folded for forming a shade-slat loop or socket in the material having two bends with an inturned end extending within the loop.

19. In a machine for making window-shades, the combination

with a frame, of means for holding shade material on the frame, feeding means for the material, knives for slitting the material lengthwise thereof, means for cutting the material transversely, together with folding and creasing means comprising two independently-movable folding-blades, one working in advance of the other, and independent creasing means having movable members acting on the material to finish the creases after the blades have folded the same.

20. In a machine for making window-shades, the combination with a frame, of means for holding a roll of shade material on the frame, feeding means for the material, means for rotating a shade-roller for winding the material thereon, means for cutting the material transversely, together with folding and creasing means comprising independently-movable folding-blades, and independent creasing means having movable members acting on the material to finish the creases after the blades have folded the same.

21. In a machine for making window-shades, the combination with a frame, of means for holding a roll of shade material on the frame, means for feeding the material, means for rotating a shade-roller for winding the material thereon, knives for slitting the material lengthwise thereof, means for cutting the material transversely, together with mechanism for folding and creasing the material at two distinct points for forming the shade-slat loop.

22. In a machine for making window-shades, the combination with a frame, of means for holding a roll of shade material on the frame, means for feeding the material, means for rotating a shade-roller for winding the material thereon, knives for slitting the material lengthwise thereof, means for cutting the material transversely, folding and creasing means comprising two independently-movable folding-blades, one working in advance and at a distinct point from the other, and independent creasing means having movable members acting on the material to finish the creases after the blades have folded the same, together with means for moving the creasing devices and blades independently of each other.

23. In a machine for making window-shades, the combination with means for holding shade material, of a device for trimming the material lengthwise thereof, together with mechanism for forming a shade-slat loop or socket having two bends with an inturned end extending within the loop, and a movable knife adapted to cut the material transversely.

24. In a machine for making window-shades, the combination with means for holding shade material, of means for winding the material on a shade-roller, means for trimming the material lengthwise thereof, a knife movable transversely of the machine to cut the material transversely, together with mechanism for forming a shade-slat loop or socket having two bends with an inturned end extending within the loop.

25. In a machine for making window-shades, the combination with means for holding shade material, of means for forming a shade-slat loop or socket, means for cutting the material transversely, together with a tension device comprising two rotatable rollers one of which is yieldingly forced toward the other.

26. In a machine for making window-shades, the combination with a frame and means for holding a web of shade material on the frame, of creasing devices having movable members, together with two folding devices adapted to move simultaneously one in advance of the other and coacting with said creasing devices for forming a loop for the shade-slat.

27. In a machine of the character described, the combination with a frame and means for holding shade material on the frame, of creasing devices having movable members, together with two folding devices adapted to move simultaneously one in advance of the other and coacting with said creasing devices to form two distinct folds and forming a loop for the shade-slat having an inturned end extending within the said loop.

28. In a machine of the character described, the combination with a frame, means for holding a web of shade material thereon, of creasing means having a fixed member and two movable members, means for moving the goods into the space between said members, together with independent movable means for operating the movable members of the creasing means and forming a loop having two bends with a short end extending within said loop.

29. In a machine of the character described, the combination with a frame, of means for folding and creasing shade material transversely thereof and forming a loop for the shade-slat, comprising creasing means having movable and fixed members and two folding devices for forcing the goods between the creasing means, the said folding devices operating one in advance of the other on the material at two distinct points to form separate folds.

30. In a machine for making window-shades, the combination with means for holding shade material, of two folding-blades, and means for giving one blade a longer movement than the other.

31. In a machine for making window-shades, the combination with means for holding shade material of two reciprocatory folding-blades, creasing devices for finishing the folds made by the blades, and means for moving the blades to form one fold deeper than the other.

32. In a machine for making window-shades, the combination with means for holding shade material, of two folding-blades forming two distinct folds in the material, and means for moving one blade to form a deeper fold than the other.

33. In a machine for making window-shades, the combination with means for holding shade material, of devices forming two folds of different depths in the material.

34. In a machine for making window-shades, the combination with means for holding shade material of devices forming two distinct folds in the material, and independent movable devices for clamping the folds to finish the creasing.

35. In a machine for making window-shades, the combination with means for holding shade material, of creasing devices, a cross-head movable toward and from the same, a folding-blade independent of the head, a second blade movable with the head, and means for imparting a longer movement to one blade than the other.

36. In a machine for making window-shades, the combination with means for holding shade material, of two reciprocatory folding-blades yieldingly held together and acting on the material at two distinct points, one of said blades forming a deeper fold in the material than the other.

37. In a machine for making window-shades, the combination with means for holding shade material, of a cross-head, a folding-blade carried directly by the cross-head, a second folding-blade yieldingly held to said cross-head, and means for giving a greater movement to the yieldingly-held blade than to the cross-head.

38. In a machine for making window-shades, the combination with means for holding shade material, of creasing devices having movable members, a cross-head movable toward the same, a blade carried directly by the cross-head, a second blade yieldingly held to the cross-head and normally movable therewith, together with mechanism for imparting a greater movement to the yieldingly-held blade than to the cross-head.

39. In a machine for making window-shades, the combination with means for holding shade material, of creasing devices having movable members, two folding devices adapted to move simultaneously one in advance of the other and coacting with said creasing devices for forming a loop for the shade-slat, together with means for causing one folding device to form a deeper fold than the other.

40. In a machine for making window-shades, the combination with means for holding shade material, of two folding-blades acting on the material at two distinct points, together with creasing devices having movable members coacting with the blades for forming the shade-slat loop.

41. In a machine for making window-shades, the combination with means for holding shade material, of reciprocatory folding-blades acting on the material at two distinct points, creasing devices having movable members for finishing the creases after the blades have ceased to act on the material, and cams for operating the creasing devices.

42. The combination with a frame, of rockably-mounted members, means for rocking said members to crease the fabric between them, and means for moving said fabric into the space between said members prior to the rocking thereof.

43. The combination of a stationary member, a movable creaser-bar coacting therewith, a movable wall coacting with the creaser-bar, said parts serving to form two creases in a section of fabric, and means for operating said parts.

44. The combination of a stationary member, a movable creaser-bar coacting therewith, a movable wall coacting with the creaser-bar, said parts serving to form two creases in a section of fabric, means for operating said parts, and means for pressing the fabric between said parts prior to the creasing movement thereof.

45. The combination of a stationary member, a movable creaser-bar coacting therewith, a movable wall coacting with the creaser-bar, said parts serving to form two creases in a section of fabric, means for operating said parts, and two blades serving to press said fabric between said parts prior to the creasing action thereof.

46. The combination of a stationary member, a movable creaser-bar coacting therewith, a movable wall coacting with the creaser-bar, said parts serving to form two creases in a section of fabric, and means for operating said parts, such means comprising a cam bearing against one of the parts and means for mounting and operating the cam.

47. The combination with a frame, of a stationary member, a movable creaser-bar coacting therewith, a movable creaser-wall coacting with the bar, means for operating the bar and wall, a cross-head, a blade carried directly thereby, and a second blade yieldingly mounted on the cross-head, said blade coacting with the creaser bar and wall.

48. The combination with creasing devices, of a cross-head movable toward and from the same, a blade carried directly by the cross-head, and a second blade carried yieldingly thereby.

49. The combination with creasing devices, of a cross-head movable toward and from the same, a blade carried directly thereby, a second blade carried movably on the cross-head, a spring actuating the second blade, a spring actuating the cross-head, and means for operating the cross-head and the second-named blade successively.

50. The combination with means for holding shade material, of creasing devices having movable members, a cross-head movable toward and from the same, a folding-blade carried directly by said cross-head, a second blade adapted to act upon the material at a point distinct from the first-mentioned blade, a yielding connection between one of the blades and the cross-head whereby said blade and cross-head may move in unison or one blade permitted to move independently of the cross-head, means for operating the cross-head and blades so as to force the material between the creasing devices, and means for actuating the movable members of the creasing devices.

51. The combination with means for holding shade material, of creasing devices having movable members, a reciprocatory cross-head movable toward and from the same, a folding-blade carried directly by said cross-head, a second blade adapted to act upon the material at a point distinct from the first-mentioned blade, springs forming a yielding connection between one of the blades and the cross-head whereby said blade and cross-head may move in unison or one blade permitted to move independently of the cross-head, means for operating the cross-head and blades so as to give one blade a longer movement than the cross-head and to force the material between the creasing devices, and means for actuating the movable member of the creasing devices.

52. The combination with creasing devices, of a cross-head movable toward and from the same, a blade carried directly thereby, a second blade carried movably on the cross-head, a spring actuating the second blade, a spring actuating the cross-head, means for operating the cross-head and the second-named blade successively, said means for operating the cross-head and second blade comprising a treadle, an extensive connection between the treadle and cross-head, and a connection between the treadle and second blade, the latter connection permitting a certain independent movement of the treadle.

53. The combination with a frame, of a stationary member, a rocking creaser-bar coacting therewith, a swinging wall coacting with the creaser-bar, means for operating said bar and wall, a cross-head, a blade carried thereby, a rod in connection with the cross-head, a spring bearing between the cross-head and creaser-bar, a second spring bearing between the creaser-bar and frame, a second blade movably mounted on the cross-head, a spring acting between the second blade and cross-head, a rod in connection with the second blade, and means for successively moving the said rods.

54. The combination with a frame having means for carrying and operating on a shade fabric, of a guide, a bearing adjustable thereon, and serving to carry one end of the shade-roller, a second bearing adjustable on the guide, a head revolubly mounted in the bearing and capable of engaging the other end of the shade-roller, and means for revolving the head.

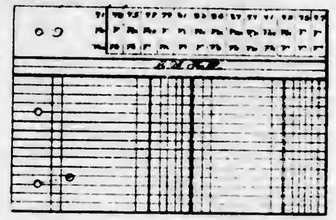
55. The combination with a frame having means for carrying and operating on a shade fabric, of a guide, a bearing adjustable thereon, and serving to carry one end of the shade-roller, a second bearing adjustable on the guide, a head revolubly mounted on the bearing and capable of engaging the other end of the shade-roller, means for revolving the head, said means comprising a revolubly-driven sleeve, and a shaft in connection with the head and slidably fitted in the sleeve, said sleeve and shaft being engaged to drive the one from the other.

56. The combination of a framing, two cutting devices mounted at the sides of the framing respectivly to trim the edges of a length of fabric, creasing means mounted on the framing to which the fabric is passed, as it moves from the cutting devices, and means for operating the cutting and creasing devices.

57. The combination of a framing, two cutting devices mounted at the sides of the framing respectively to trim the edges of a length of fabric, creasing means mounted on the framing to which the fabric is passed as it moves from the cutting devices, means for operating the cutting and creasing devices, and a strip or bar extending transversely of the framing between the cutting and creasing devices and adapted to have a knife run over it to sever the fabric into lengths.

58. The combination of a framing, a transverse guide thereon, a bracket adjustably mounted on the guide, two coacting rotary cutters carried by the bracket, two shafts on which said cutters are respectively splined, and means for driving the shafts.

12,446. SELF-INDEXING LOOSE-LEAF LEDGER. SIMEON KIRTLEY, Columbia, Mo. Filed Sept. 11, 1905. Serial No. 278,051. Original No. 767,200, dated Aug. 9, 1904.



Claim.—1. A series of original loose self-indexing sheets having a portion of their edges cut away, and portions of said cut-away sheets being exposed and having suitable identifying characters upon the said exposed portions, in combination with an additional series of transfer-sheets interchangeable with said original sheets and provided with identifying characters the same as those of the original sheets, and having detachable cut-away portions separated from their main bodies by perforated lines, substantially as specified.

2. A series of original loose self-indexing sheets having a portion of their edges cut away, and portions of said cut-away sheets being exposed and having suitable identifying characters upon the said exposed portions, in combination with an additional series of transfer-sheets interchangeable with said original sheets and provided with identifying characters the same as those of the original sheets, and having detachable cut-away portions separable from the bodies of the transfer-sheets by a line of perforations, substantially as specified.

3. A series of original loose self-indexing sheets having a portion of their edges cut away, and portions of said cut-away sheets being exposed and having suitable identifying characters upon the said exposed portions, in combination with an additional series of transfer-sheets interchangeable with said original sheets and provided with identifying characters the same as those of the original sheets, and having detachable cut-away portions separable from the bodies of the transfer-sheets by a line of perforations; extra duplicate perforated transfer-sheets and temporary bindings for all the sheets, substantially as specified.

4. A self-indexing ledger or book, provided with interchangeable loose cut-away leaves for the letters of the alphabet, portions of the said cut-away leaves being exposed, the initial letter with second and third letters of names placed on certain of said exposed portions, and the initial letter placed only with the second letter on certain of said exposed portions, and having a space adjacent thereto for the insertion of the third letter of the names, and the initial being placed alone on certain of said exposed portions and having spaces adjacent thereto for the insertion of the second and third letters of names which cannot be anticipated, different identifying characters on the exposed portions of the different cut-away leaves; and an additional series of interchangeable loose cut-away sheets adapted to be located in a transfer ledger or book and provided with leaves and identifying characters the same as those of the original ledger or book, in combination with a third series of insert blank sheets identical in size and shape with those previously mentioned but devoid of an index, and a fourth series of blank sheets adapted to receive additional or subsequently-occurring accounts and identical with those of the third series, except cut back one step farther so as to expose the first indexed sheet beneath, and also provided with identifying characters to distinguish them from each other, substantially as specified.

5. The combination of two self-indexing loose-leaf ledgers or books, one of which is an original and the other a transfer book each having a separate series of blank sheets which are cut away so as to expose the sheet beneath them, and the sheets of both books provided upon said cut-away portions with corresponding identifying charac-

ters, and a third series of insert blank sheets identical in size and shape with those previously mentioned, but devoid of an index, substantially as specified.

6. The combination of two self-indexing loose-leaf ledgers or books, one of which is an original and the other a transfer book each having a separate series of blank sheets which are cut away so as to expose the sheet beneath them, and the sheets of both books provided upon said cut-away portions with corresponding identifying characters, a third series of insert blank sheets identical in size and shape with those previously mentioned but devoid of an index, and a fourth series of blank sheets adapted to receive additional or subsequently-occurring accounts and identical with those of the third series, except cut back one step farther so as to expose the first indexed sheet beneath, and also provided with identifying characters to distinguish them from each other, substantially as specified.

7. The combination of two self-indexing loose-leaf ledgers or books, one of which is an original and the other a transfer book each having a separate series of blank sheets which are cut away so as to expose the sheets beneath them, and the sheets of both books provided upon said cut-away portions with the first letter of the names to be indexed, and having a blank space adjacent thereto for additional characters, the said original book having also a third series of insert blank sheets identical in size and shape with those previously mentioned but devoid of an index, and a fourth series of blank sheets adapted to receive additional or subsequently-occurring accounts and identical with those of the third series, except cut back one step farther so as to expose the first indexed sheet beneath, and also provided with identifying characters to distinguish them from each other, substantially as specified.

8. The combination of two self-indexing loose-leaf ledgers or books, one of which is an original and the other a transfer book each having a separate series of blank sheets which are cut away so as to expose the sheets beneath them, and the sheets of both books provided upon said cut-away portions with the first two letters of the names to be indexed, and having a blank space adjacent thereto for additional characters, the said original book having also a third series of insert blank sheets identical in size and shape with those previously mentioned but devoid of an index, and a fourth series of blank sheets adapted to receive additional or subsequently-occurring accounts and identical with those of the third series, except cut back one step farther so as to expose the first indexed sheet beneath, and also provided with identifying characters to distinguish them from each other, substantially as specified.

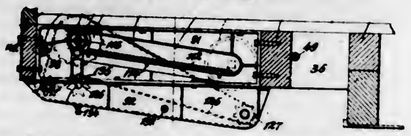
9. The combination of two self-indexing loose-leaf ledgers or books, one of which is an original and the other a transfer book each having a separate series of blank sheets which are cut away so as to expose the sheet beneath them, and the sheets of both books provided upon said cut-away portions with the first three letters of the names to be indexed, and having a blank space adjacent thereto for additional characters, the said original book having also a third series of insert blank sheets identical in size and shape with those previously mentioned but devoid of an index, substantially as specified.

10. The combination of two self-indexing loose-leaf ledgers or books, one of which is an original and the other a transfer book each having a separate series of blank sheets which are cut away so as to expose the sheets beneath them, and the sheets of both books provided upon said cut-away portions with the first three letters of the names to be indexed, and having a blank space adjacent thereto for additional characters, the said original book having also a third series of insert blank sheets identical in size and shape with those previously mentioned but devoid of an index, and a fourth series of blank sheets adapted to receive additional or subsequently-occurring accounts and identical with those of the third series, except cut back one step farther so as to expose the first indexed sheet beneath, and also provided with identifying characters to distinguish them from each other, substantially as specified.

11. The combination of two self-indexing loose-leaf ledgers or books, one of which is an original and the other a transfer book each having a separate series of blank sheets which are cut away so as to expose the sheet beneath them, and the sheets of both books provided with the first three letters of the names to be indexed, and having a blank space adjacent thereto for additional characters, a third series of insert blank sheets identical in size and shape with those previously mentioned but devoid of an index, substantially as specified.

12. The combination of two self-indexing loose-leaf ledgers or books, one of which is an original and the other a transfer book each having a separate series of blank sheets which are cut away so as to expose the sheet beneath them, and the sheets of both books provided with the first three letters of the names to be indexed, and having a blank space adjacent thereto for additional characters, a third series of insert blank sheets identical in size and shape with those previously mentioned, but devoid of an index, substantially as specified.

12,447. CAR. WILLIAM A. CASWELL, Chicago, Ill., assignor, by mesne assignments, to National Coal Dump Car Company, Chicago, Ill., a Corporation of South Dakota. Filed Jan. 5, 1906. Serial No. 294,799. Original No. 808,394, dated Dec. 5, 1905.



Claim.—1. The car having all its longitudinal sills located centrally and having a level and unobstructed floor above the plane of the sills, extending from end to end and from side to side of the car, said floor embodying two series of outwardly-opening doors hinged to the outside of the sills.

2. The car all whose longitudinal sills are located centrally, and provided with a level unobstructed floor above the sills, extending from end to end, and side to side of the car, such floor embodying outwardly-opening doors hinged outside of the line of the sills.

3. The car having all its longitudinal sills located centrally, and having a series of dump-doors in its floor extending from end to end of the car and hinged to the outside of the sills.

4. The car having all its longitudinal sills located centrally, and also having a level floor from end to end, the side portions of said floor being formed by doors hinged to the outside of the sills and opening at their outer edges.

5. The car having all its longitudinal sills located centrally and also having a level floor from end to end, the side portions of said floor embodying doors hinged to the sills and opening at their outer edges and located over the trucks.

6. The car having its longitudinal sills located centrally and also having a level floor extending from end to end of the car and outwardly-opening dump-doors in said floor, said doors being provided with supports adapted to control the extent of their opening, and to permit only a partial opening when that is desired.

7. The car whose longitudinal underframing consists of center and intermediate sills, and whose side walls are braced by heavy diagonal braces extending from stake to stake, and entered at their upper ends under bent-over portions of the stakes, substantially as specified.

8. The car having stakes 46 with bent-over portions 45, and diagonal braces entered under said bent-over portions, substantially as specified.

9. The car having only centrally-located sills, a level and unobstructed floor throughout, and a superstructure provided with a base-strip, said floor embodying a series of outwardly-opening doors located outside the sills and extending under said base-strip.

10. The combination with the center and intermediate sills, of a bolster consisting of a top bar with its ends bent down, a bottom bar, outside casting 58, the webbed casting 66, and the casting 68, substantially as specified.

11. The combination with the center and intermediate sills, of a bolster-bar, outside casting 58, webbed casting 66, and the stakes passing down through the forked ends of the top bar and the webbed casting, substantially as specified.

12. The car having its headers or cross-frame members provided with webbed castings which extend from the intermediate sills outward to the stakes and support the latter, substantially as specified.

13. The car having headers embodying webbed castings extending outward from the intermediate sills and beams below said castings extending outward from the center sills, substantially as specified.

14. The header consisting of the webbed casting 77, the beam 75 and the outside end casting, substantially as specified.

15. The header consisting of the webbed casting 77, the beam 75, the outside end casting, and the shell-casting 83, substantially as specified.

16. The car whose longitudinal load-supporting members consist solely of the center sills, the intermediate sills and the braced side walls of the box, and provided with dump-doors in its floor along its side walls opening toward the outside of the track, substantially as specified.

17. The combination with the dump-door of a car, of means for supporting the swinging edge of the door when closed, consisting of rollers movable downward back from said edge, substantially as specified.

18. The combination with the dump-door of a car, of means for supporting the swinging edge of the door when closed, consisting of rollers movable downward back from said edge, and a shaft supporting said rollers, substantially as specified.

19. The combination with the dump-door of a car, of a shaft and rollers thereon for supporting the swinging edge of the door, said shaft being movable bodily dowaward and back from said edge, substantially as specified.

20. The combination with the dump-door of a car, of a shaft and rollers thereon for supporting the swinging edge of the door, said shaft being movable bodily downward and back from said edge, and means for so moving said rollers, substantially as specified.

21. The combination with the dump-door of a car, of a shaft and rollers thereon for supporting the swinging edge of the door, said shaft being movable bodily downward and back from said edge, and means for moving said shaft, substantially as specified.

22. The combination with the dump-door of a car, consisting of rollers located below the door and movable from their normal positions in which they hold the door closed, and acting to support the door in all of its positions, substantially as specified.

23. The combination with the dump-door of a car, of a shaft and rollers thereon for supporting the swinging edge of the door, said shaft being movable bodily downward and backward and being also rotatable, substantially as specified.

24. The combination with the dump-door of a car, of a shaft and rollers thereon for supporting the swinging edge of the door, said shaft being movable bodily downward and backward and being also rotatable, and means for rotating the shaft, substantially as specified.

25. The combination with the dump-door of a car, of a shaft and rollers thereon for supporting the swinging edge of the door, said shaft being movable bodily downward and backward and being also rotatable, means for rotating the shaft, and racks and pinions for moving the shaft bodily, substantially as specified.

26. The combination with the dump-door of a car, of a shaft and rollers thereon for supporting the swinging edge of the door, said shaft being movable bodily downward and backward and being also rotatable, and the rollers being loosely mounted on the shaft, substantially as specified.

27. The combination with the dump-door of a car, of a shaft and rollers thereon for supporting the swinging edge of the door, said shaft being movable bodily downward and backward and being also rotatable, means for rotating the shaft, stationary racks supported in the cross-traming, and pinions on the shaft, whereby the rotation of the shaft causes its bodily movement, substantially as specified.

28. The combination with the cross-frame members of the car and a longitudinal series of dump-doors, of a shaft passing through said members, and carrying loose rollers for supporting the doors, inclined racks in said members meshing with pinions on the shaft, and means for rotating the shaft and giving it a bodily movement to open the doors, substantially as specified.

29. The car, the underframing whereof consists of center and intermediate sills, end sills, bolsters, needle-beams and headers, the latter located between the bolsters and needle-beams, substantially as specified.

30. The car having a longitudinal series of dump-doors along each of its sides, and headers or cross-frames extending between the doors of each series and affording them lateral support.

31. The car having a longitudinal series of dump-doors along its sides, headers or cross-frame members between adjacent doors, and a shaft extending through and sustained by said headers and supporting the doors, substantially as specified.

32. The car having a longitudinal series of dump-doors along its sides, headers or cross-frame members between adjacent doors, and a shaft extending through and sustained by said headers and supporting the doors, said shaft being also supported at its outer end from the end sill, substantially as specified.

33. The car having its bolsters and headers all provided with cast-metal ends having formed in them inclined ways for the door-supporting shafts, substantially as specified.

34. The car having its bolsters and headers all provided with cast-metal ends having inclined openings and racks for the door-supporting shafts and their operating-pinions, substantially as specified.

35. The car wherein are combined the dump-doors, the cross members between the doors having cast-metal ends with inclined openings and racks, and the door-supporting shafts moving through said openings and having pinions meshing with the racks, substantially as specified.

36. The car wherein are combined the dump-doors, the cross members between the doors having cast-metal ends with inclined openings and racks, the end sill having a casting also provided with an inclined opening and rack, and the door-supporting shaft moving through said openings and having pinions meshing with the racks, substantially as specified.

37. The combination with the end sill and bodily-movable door-supporting shaft, of the casting 91 applied to said sill and provided with an opening in which the end of the shaft may be supported and be moved, substantially as specified.

38. The car having an endwise-movable door-supporting shaft located wholly inside the end sill, in combination with such end sill having an opening therethrough permitting the removal of the shaft when in one of its positions, substantially as specified.

39. The door-supporting shaft having the rollers and pinions carried by it readily releasable so they may be slipped off, and itself removable endwise from the car, in combination with the frame members through which the shaft passes, substantially as specified.

40. The combination with the doors and the cross-frame members having inclined openings therethrough, of a bodily-movable and rotating door-supporting shaft sustained in said openings and removable endwise therefrom, substantially as specified.

41. The car having its side walls braced by braces 42 whose lower ends are supported upon the bolsters and needle-beams, substantially as specified.

42. The car having its side walls braced by braces 42 supported at their lower ends upon bolsters and needle-beams, and themselves supporting the stakes of the intermediate headers, substantially as specified.

43. In a car of the class described, the combination of a supporting-frame, a drop-bottom formed of a plurality of swinging doors secured to the supporting-frame and rolling mechanism adapted to contact such doors to close and hold the same in closed position, substantially as described.

44. In a car of the class described, the combination of a supporting-frame portion, a drop-bottom portion therefor formed of a plurality of swinging sections pivotally secured together at each side of a longitudinal center of the car, a reciprocating bar extending longitudinally of the car, and movable transversely thereof in engagement with each swinging section, and means for reciprocating said bar to open and close the swinging sections, substantially as described.

45. In a car of the class described, the combination of a supporting-framework provided with a rock bottom formed of a plurality of swinging sections pivotally secured thereto, a reciprocating bar having a bearing portion in the supporting-framework of the car and contacting the under side of each swinging section, and means for reciprocating said bar to open and close the swinging sections, substantially as described.

46. In a car of the class described, the combination of a supporting bottom frame, a drop-floor section hinged in said frame, means supporting said section and contacting with its under surface and movable back and forth between its hinged edge and its swinging edge, and regulating the opening by the extent of its movement, means for operating the said supporting means, and means for arresting said operating means at an intermediate position.

47. In a car of the class described, the combination of a supporting bottom frame, a drop-floor section hinged in said frame, means supporting the swinging side of the section and contacting with its under surface and movable from the hinged side toward the swinging side to close the section and regulating the door by the position to which the supporting means are moved, and means for operating said supporting means.

48. In a car of the class described, the combination of a supporting bottom frame, a drop-floor section hinged to a longitudinal member of the frame, means supporting said section and contacting with its under surface and movable toward and from said longitudinal frame member in opening and closing said section, said means being sustained in the cross-framing of the bottom, and means for operating said supporting means.

49. In a car of the class described, the combination of a supporting bottom frame, a drop-floor section hinged to a central longitudinal member of the frame and opening at its outer edge, means

supporting said section and contacting with its under surface and movable outward from said frame member inclosing the section, said means being sustained in the cross-framing in the bottom, and means for operating said supporting means.

50. The combination with the hinged dumping-door of a flat-bottom car, of means for supporting the door in its closed and open positions, such means consisting of a rigid bar located under and extending lengthwise across the door and movable toward the opening side of the door to close the same and toward the hinged side to open it, supports for said bar at each end of the door, and means for controlling said bar.

51. The combination with a hinged dumping-door of a flat-bottom car, of means for supporting the door in its closed and open positions, such means consisting of a rigid bar located under and extending lengthwise across the door and movable toward the opening side of the door to close the same and toward the hinged side to open it, supports for said bar at each end of the door, and means for controlling said bar adapted to hold it rigidly in intermediate position.

52. The combination with a hinged dumping-door of a flat-bottom car, of means for supporting the door in its closed and open positions, such means consisting of a rigid bar having a bearing contact with the under side of the door and extending lengthwise across it, and movable toward the hinged side of the door to open it, and toward the opening side to close it, supports for said bar at each end of the door, and means for controlling the bar.

53. The combination with a hinged dumping-door of a flat-bottom car, of means for supporting the door in its closed and open positions, such means consisting of a rigid bar extending lengthwise across the door and having a bearing contact with it at each end, said bar being movable toward the opening side of the door to close it and toward the hinged side to open it, supports for said bar at each end of the door, and means for controlling the bar.

54. The combination with a hinged dumping-floor section, of a rigid bar extending across the section and movable transversely of the section and always in bearing contact therewith, means for controlling said bar in its different positions, and supports for the bar located outside the section.

55. The combination with a hinged dumping-floor section, of a rigid bar extending across the section and movable transversely of the section and always in bearing contact therewith, means for controlling said bar in its different positions, and ways outside the section on which said bar rests and travels.

56. In a dump-car, the combination of a car-frame, a dumping-door pivotally mounted in such car-frame movable to open and closed position, a shaft reciprocatingly mounted beneath and supporting such door in both open and closed positions, and means for supporting the shaft and thereby the dumping-door in both open and closed positions.

57. In a dump-car, the combination of a car-frame, dumping-doors pivotally mounted in such car-frame movable to open and closed positions, a shaft reciprocatingly mounted beneath and supporting such doors, and supporting mechanism having upwardly and outwardly inclined supporting-surface portions upon which such shaft is mounted and provided with looped portions at the lower end of such inclined portions for limiting the movement of the shaft and thereby the dumping-doors.

58. In a car, the combination of a car-frame having longitudinal sill mechanism, end sills and transverse beams between such end sills, a dumping-door secured to the car-frame movable to open and closed positions, and dumping-door-supporting mechanism supported by such transverse beams said supporting mechanism being movable longitudinally of the door.

59. In a car, the combination of a car-frame having longitudinal sill mechanism and transverse beams mounted between the ends of the car-frame, dumping-doors secured to such car-frame movable to open and closed positions, and door-operating mechanism mounted in such transverse beams and connected with the dumping-doors said supporting mechanism being movable longitudinally of the door.

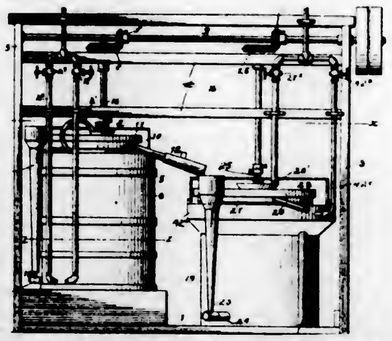
60. In a car, the combination of a car-frame having transverse beams, dumping-doors secured to such car-frame movable to open and closed positions, and door supporting and operating shaft mechanism beneath the dumping-doors and supported by the transverse beams said supporting mechanism being movable longitudinally of the door.

61. In a car, the combination of a car-frame having transverse beams mounted between the ends of the car, dumping-doors secured to the car-frame movable to open and closed positions, shaft mechanism mounted in such transverse beams beneath the dumping-doors and operatively connected therewith for opening and closing the doors and supporting them in closed position, and means for operating such shaft mechanism said shaft mechanism being movable longitudinally of the door.

62. In a car, the combination of a car-frame having longitudinal sill mechanism, end sills and transverse beams secured to such longitudinal sills and extending transversely of the car, dumping-doors mounted in the car-frame on opposite sides of its longitudinal center movable to open and closed positions and having their inner edges hinged to the car-frame forming flat-bottom portions for the car when in closed position, and door operating and supporting shafts mounted in the transverse beams beneath the dumping-doors and operatively connected therewith said shafts being movable longitudinally of the door.

63. In a car, the combination of a car-frame having transverse beams between the ends thereof, dumping-doors secured to such car-frame movable to open and closed positions, and shafts extending longitudinally of the car supported by such transverse members of the car-frame and in operative engagement with the swinging sides of the dumping-doors outside their longitudinal centers for supporting them.

12,448. **APPARATUS FOR STERILIZING LIQUIDS.** John C. Miller, Canton, Ohio, assignor, by mesne assignments, to The Miller Pasteurizing Machine Co., Canton, Ohio, a Corporation of New Jersey. Filed July 17, 1903. Serial No. 166,065. Original No. 678,893, dated July 23, 1901.



Claim.—1. In an apparatus of the character described, the combination with a heater comprising a tub, two cylinders placed within the tub one within the other, one of said cylinders being provided with a feed-screw which works against the other cylinder, of a steam or hot-water pipe located within the tub exterior to the cylinders, and an injector located in the tub to eject the water therefrom and inject it into the innermost cylinder whereby a uniform temperature is maintained between the two cylinders, substantially as set forth.

2. In an apparatus of the character described, the combination with a heater comprising a tub and two cylinders placed within the tub one within the other, one of said cylinders being provided with a feed-screw which works against the other cylinder, of a steam or hot-water pipe located within the tub exterior to the cylinders, and an injector located within the tub to eject the water therefrom and inject it into the innermost cylinder whereby a uniform temperature is maintained between the two cylinders, substantially as set forth.

3. In an apparatus of the character described, the combination with a heater comprising a tub and two cylinders placed within the tub one within the other, of a steam or hot-water-discharge pipe located in the bottom of the tub exterior to the cylinders, and an injector leading from the tub to the innermost cylinder, substantially as set forth.

4. In an apparatus of the character described, the combination with a heater comprising a tub and two cylinders placed within the tub one within the other, of a steam or hot-water coil located in the bottom of the tub exterior to the cylinders, a vertical pipe extending downwardly and in close proximity to the bottom of the innermost cylinder, and an injector leading from the tub and adapted to discharge into the vertically-disposed pipe within the cylinder, substantially as set forth.

5. The combination of a cooler comprising an inner and outer cylinder, the inner cylinder being provided with a feed-screw to engage the inner wall of the outer cylinder, the outer cylinder being provided with an external tortuous water-passage and with an upper trough which communicates with the space formed between the two cylinders, and the inner cylinder being provided with a lateral flange or guard extending over said trough, a second trough arranged around the outer cylinder and extending laterally beyond the first-named trough and adapted to receive the overflow from the inner cylinder, a water-pipe communicating with the inner cylinder and the tortuous passage of the outer cylinder, a pipe communicating with the lower end of the tortuous passage and the last-named trough, substantially as set forth.

6. In a mechanism for treating milk and other liquids, the combination of an outer water-holding vessel having a thin wall on the outer side of a milk-passage, a duct leading milk to the bottom of the said milk-passage, a trough or receptacle for the milk at the upper end of the said passage, an inner rotary vessel adapted to hold a body of water and having a thin wall forming the inner side of the milk-passage, and a shield carried by the said inner vessel and extending outward over the said milk-trough and turned down to leave its outer edge in vertical lines which are outside of the vertical lines of the milk-trough and adapted to direct the overflow from the inner water-holding vessel into the outer one, substantially as set forth.

7. In an apparatus for treating milk, the combination of an inner water-holding vessel, a second vessel, the adjacent walls of said vessels forming a relatively thin passage-way for the milk between them, and the said inner vessel being adapted to hold a body of water normally cut off from the outer vessel, means for rotating one of said vessels relatively to the other one, an outer water-holding vessel arranged to hold a body of water around said second vessel, a water-heater in one of said water-holding vessels adapted to heat the water therein approximately to a predetermined temperature, and a water-heater adapted to continuously supply heated water to the second water-holding vessel of substantially the same temperature as that of the heated water in the first water-holding vessel.

8. In an apparatus for treating milk, the combination of an inner water-holding vessel and an outer water-holding vessel with their adjacent walls arranged to form a relatively thin passage-way for the milk between them, the inner water-holding vessel being adapted to hold a body of water normally cut off from the said body of water in the said outer water-holding vessel, a water-heater in one of said vessels adapted to raise the temperature of the water therein to the desired degree, a water-heater for the other vessel adapted to continuously deliver heated water to it from the first vessel, and means for rotating one of said vessels relatively to the other one.

9. In an apparatus for treating milk, the combination of an inner water-holding vessel, an outer water-holding vessel, the inner wall of the latter and the outer wall of the fomer being arranged to provide a relatively thin passage-way for the milk between them, the said inner water-holding vessel being adapted to hold a body of water normally cut off from the body of water in the outer water-holding vessel, means for continuously supplying water to the inner water holding vessel near the bottom thereof, means for continuously supplying water to the outer water-holding vessel, means for feeding the milk to the bottom of said milk passage-way, means for collecting the milk at the top of said milk passage-way, and means for rotating one of said water-holding vessels relatively to the other one, substantially as set forth.

10. In an apparatus for pasteurizing or sterilizing milk without injuring its cream-giving qualities, the combination of means for causing the milk to be treated to travel in a relatively attenuated stream or film, means for suddenly and uniformly heating all of the particles of said milk while it is so traveling, means for causing said milk after it has been heated to flow in a second relatively attenuated stream or film, means for immediately directing the said heated milk from the delivery-point of the said first stream or film to the receiving-point of the said second stream or film, and means for suddenly and continuously without pause removing the heat from the milk while it is traveling in said second stream or film.

11. In an apparatus for treating milk to pasteurize or sterilize it without injuring its cream-giving qualities, the combination of two closely-adjacent heat-conducting walls arranged to form a relatively thin passage-way for the milk between them, means for substantially uniformly heating said walls to the same desired degree, means for introducing the milk to be treated between said walls, means for causing it to flow rapidly therebetween to the point of its delivery from said passage-way, whereby all of the milk particles are suddenly and uniformly heated, a cooler having a heat-conducting surface, means for immediately directing the uniformly-heated milk from the delivery-point of said heated-milk passage-way to the said heat-conducting surface of the cooler, means for causing the milk to travel along said cooling-surface in a relatively attenuated stream or film, and means for maintaining the said cooling-surface at the necessary degree of temperature to suddenly and continuously without pause remove the said heat from all of the particles of the milk and to reduce the temperature of the milk to the desired degree.

12. In an apparatus for treating milk to pasteurize or sterilize it without injuring its cream-giving qualities, the combination of two closely-adjacent heat-conducting walls arranged to form a relatively thin passage-way for the milk between them, means for substantially uniformly heating said walls to the same desired degree, means for introducing the milk to be treated between said walls, means for causing it to flow rapidly therebetween in a circuitous path to the point of its delivery from said passage-way, whereby all of the milk particles are suddenly and uniformly heated, a cooler having a heat-conducting surface, means for immediately directing the uniformly-heated milk from the delivery-point of said milk passage-way to the said heat-conducting surface of the cooler, means for causing the milk to travel along said cooling-surface in a relatively attenuated stream or film, and means for maintaining the said cooling-surface at the necessary degree of temperature to suddenly and continuously without pause remove the said heat from all of the particles of the milk and to reduce the temperature of the milk to the desired degree.

13. In an apparatus for pasteurizing or sterilizing milk without injuring its cream-giving qualities, the combination of a pair of heat-conducting walls arranged to form a relatively thin passage-way for the milk to be treated between them, means for substantially uniformly heating the said walls to the same desired degree, means for introducing the milk to be treated between said walls, means for causing the milk to flow rapidly therebetween to the point of its delivery from said passage-way whereby all of the particles are suddenly and uniformly heated, a second pair of heat-conducting walls arranged to form a second relatively thin passage-way for the milk between them, means for cooling each of said last-described walls to the desired temperature, means for conducting the heated milk from the said first milk passage-way immediately to the receiving-point of the second milk passage-way, and means for causing the milk to flow rapidly and continuously through the said second passage-way, whereby the heat is suddenly and continuously removed from all of its particles.

14. In an apparatus for pasteurizing or sterilizing milk without injuring its cream-giving qualities, the combination of a pair of heat-conducting walls arranged to form a relatively thin passage-way for the milk to be treated between them, means for substantially uniformly heating the said walls to the same desired degree, means for introducing the milk to be treated between the said walls, means for causing the particles of milk to flow rapidly in a circuitous path therebetween to the point of their delivery from said passage-way whereby all of its particles are suddenly and uniformly heated, a second pair of heat-conducting walls arranged to form a second relatively thin passage-way for the milk between them, means for cooling each of said last-described walls to the desired temperature, means for conducting the heated milk from the said first milk passage-way immediately to the receiving-point of the said second milk passage-way, and means for causing the milk to flow rapidly and continuously through the said second passage-way whereby the heat is suddenly and continuously without pause removed from all of said particles.

15. In an apparatus for pasteurizing or sterilizing milk without injuring its cream-giving qualities, the combination of an inner water-holding cylinder, an outer cylinder, the adjacent walls of said cylinders forming a relatively thin passage-way for the milk between them, means for holding a body of water around said outer cylinder, means for rotating one of said cylinders relative to the other one, means for maintaining the water around the walls of said milk passage-way heated to substantially the same temperature, means for supplying milk from a relatively high level to the bottom of said milk passage-way, means for collecting it at the top thereof, a second pair of concentric cylinders having their adjacent walls arranged to form a relatively thin passage-way for the milk between them, said passage-way being arranged at a lower level than the level of the first-described milk passage-way, means for rotating one of said last-described cylinder-walls relative to the other one, means for supplying cooling medium of the desired temperature to each of said walls, and means for immediately directing the heated milk collected at the top of the first-described milk passage-way to the bottom of said cooling passage-way.

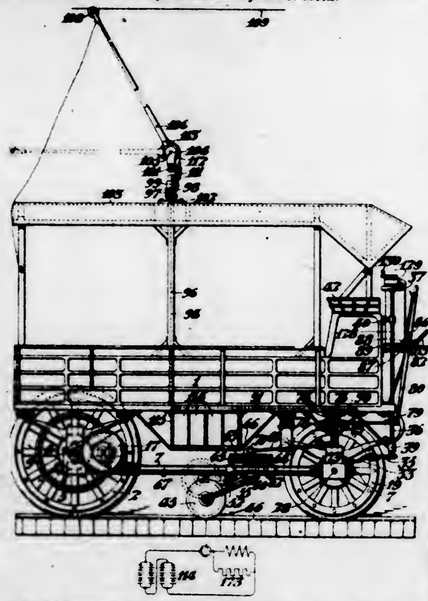
12,449. **ELECTRICALLY-PROPELLED VEHICLE.** Russell Thayer, Philadelphia, Pa. Filed July 20, 1905. Serial No. 271,804. Original No. 704,080, dated July 5, 1904.

Claim.—1. An automobile provided with an electric motor and a storage battery; having wheels constructed and arranged to traverse the tracks of a railway system; with a trackless road-bed independently of said system; a trolley-pole arranged to engage said main; a contact-wheel arranged to engage

37,804.

37,807. **EARTHENWARE CLOSET-BOWL.** Edward T. Webster, Milwaukee, Wis. Filed Nov. 17, 1905. Serial No. 287,902. Term of patent 14 years.

Claim.—1. An automobile provided with an electric motor and a storage battery; having wheels constructed and arranged to traverse the tracks of a railway supply system, with said motor in operative connection with said system, and, to traverse a trackless road-bed, independently of said system, with said motor in operative connection with said battery, substantially as set forth.



2. An automobile provided with an electric motor and a storage battery, having wheels constructed and arranged to traverse the tracks of a railway supply system, with said motor in operative connection with said system and said battery connected to be charged thereby, and, to traverse a trackless road-bed, independently of said system, with said motor in operative connection with said battery, substantially as set forth.

3. An automobile provided with an electric motor and a storage battery, having wheels constructed and arranged to traverse the tracks of a railway supply system, with said motor in operative connection with said system, and, to traverse a trackless road-bed, independently of said system, with said motor in operative connection with said battery; and, manually-operative means arranged to contemporaneously transfer the operative circuit connections of said motor from said system to said battery, substantially as set forth.

4. In an automobile provided with an electric motor and a storage battery; constructed and arranged to traverse the railway-tracks of a system comprising an overhead-trolley supply-main, and to traverse a trackless road-bed independently of said trolley system; a trolley-pole arranged to engage said main; and, adjustable means arranged to electrically connect said motor with the railway-tracks, substantially as set forth.

5. In an automobile provided with an electric motor and a storage battery; constructed and arranged to traverse the railway-tracks of a system comprising an overhead-trolley supply-main; and to traverse a trackless road-bed independently of said trolley system; a trolley-pole arranged to engage said main; and, an adjustable contact-wheel arranged to electrically connect said motor with the railway-tracks, substantially as set forth.

6. An automobile provided with an electric motor and a storage battery, having wheels constructed and arranged to traverse the tracks of a railway system comprising an overhead-trolley supply-main, and, to traverse a trackless road-bed independently of said trolley system; a trolley-pole arranged to engage said main; and, cooperatively-related means arranged to electrically connect said motor with said overhead main and railway-tracks, substantially as set forth.

7. In an automobile provided with an electric motor and a storage battery; constructed and arranged to traverse the railway-tracks of a system comprising an overhead supply-main, and to traverse a trackless road-bed independently of said system; a trolley-pole arranged to engage said main; a contact-wheel arranged to engage said tracks; and, manually-operative means to raise and lower said trolley-pole and contact wheel, substantially as set forth.

8. In an automobile provided with an electric motor and a storage battery; constructed and arranged to traverse the railway-tracks of a system comprising an overhead supply-main, and to traverse a trackless road-bed independently of said system; a trolley-pole arranged to engage said main; a contact-wheel arranged to engage said tracks; and, manually-operative means connecting said trolley-pole and contact-wheel arranged to contemporaneously adjust them, substantially as set forth.

9. An automobile provided with an electric motor and a storage battery, having wheels constructed and arranged to traverse the tracks of a railway supply system, with said motor in operative connection with said system, and said battery connected to be charged thereby and, to traverse a trackless road-bed, independently of said system, with said motor in operative connection with said battery; an auxiliary resistance; and means to connect said resistance in circuit with said battery during the charging operation and to eliminate said resistance from said circuit during the discharging operation, substantially as set forth.

10. An automobile provided with wheels constructed and arranged to traverse the tracks of a railway supply system, and to traverse a trackless road-bed independently of said system; a storage battery; a plurality of electric motors; means arranged to alternately effect the operation of said motors in connection with the supply-mains of said system and in connection with said battery, substantially as set forth.

11. An automobile provided with wheels constructed and arranged to traverse the tracks of a railway supply system, and to traverse a trackless road-bed, independently of said system; a storage battery; two electric motors; means arranged to alternately effect the operation of said motors in connectionwith the supply-mains of said system and in connection with said battery, substantially as set forth.

12. In an automobile constructed and arranged to traverse the railway-tracks of an overhead-trolley supply system and to traverse a trackless road-bed independently of said trolley system; a storage battery; two electric motors; and, a manually-operative controller, comprising cooperative switching means arranged to alternately effect the operation of said motors, respectively in connection with the supply-mains of said system and in connection with said battery, substantially as set forth.

13. In an automobile constructed and arranged to traverse the railway-tracks of an overhead-trolley supply system and to traverse a trackless road-bed independently of said system; a storage battery; two electric motors, respectively constructed and arranged to operate at different voltages; and means arranged to alternately effect the operation of said motors, respectively in connection with the supply-mains of said system and in connection with said battery, substantially as set forth.

14. In an automobile constructed and arranged to traverse the railway-tracks of an overhead-trolley supply system and to traverse a trackless road-bed independently of said system; a storage battery; two electric motors having alined shafts respectively in operative relation with opposite supporting-wheels of said vehicle; differential gearing connecting said shafts; and, means arranged to alternately effect the operation of said motors, respectively in connection with the supply-mains of said system and in connection with said battery, substantially as set forth.

15. In an automobile constructed and arranged to traverse the railway-tracks of an overhead-trolley supply system and to traverse a trackless road-bed independently of said system; a wheel on said vehicle comprising a metallic flange arranged to make electrical contact with one of said railway-tracks; and, a tire on said wheel arranged to insulate it from a trackless road-bed traversed by said vehicle, substantially as set forth.

DESIGNS.

37,804. SOCIETY BADGE OR BUTTON. KASIMIR STACHOWSKI, Chicago, Ill. Filed Nov. 22, 1905. Serial No. 288,004. Term of patent 7 years.

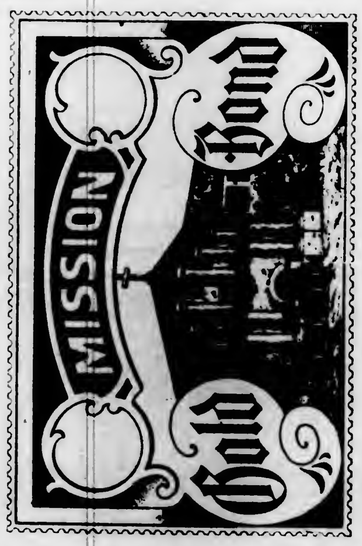
37,804.

Claim.—The ornamental design for a society badge or button, as shown.

37,805. BRACELET. JOHN BENNETT, Attleboro, Mass., assignor to Electric Chain Company, a Corporation of Maine. Filed Dec. 20, 1905. Serial No. 292,671. Term of patent 3½ years.

Claim.—The ornamental design for a bracelet, as shown.

37,806. TRADING-STAMP. SIEGMUND HERTZMANN, San Francisco, Cal., assignor to Mission Gold Bond Co., San Francisco, Cal., a Corporation of California. Filed Dec. 19, 1905. Serial No. 292,517. Term of patent 7 years.

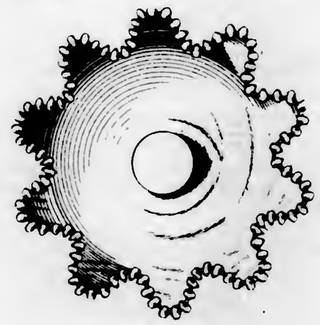


Claim.—The ornamental design for a trading-stamp, as shown.

37,807. EARTHENWARE CLOSET-BOWL. EDWARD T. WEBSTER, Milwaukee, Wis. Filed Nov. 17, 1905. Serial No. 287,902. Term of patent 14 years.

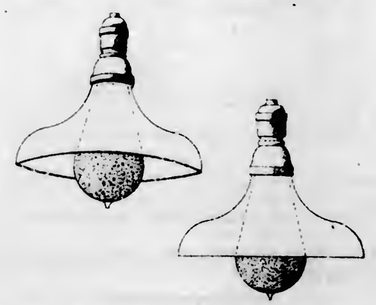
Claim.—The ornamental design for an earthenware closet-bowl, as shown.

37,808. REFLECTOR FOR ARTIFICIAL LIGHTS. OTIS A. MYGATT, New York, N. Y. Filed Dec. 5, 1903. Serial No. 183,975. Term of patent 14 years.



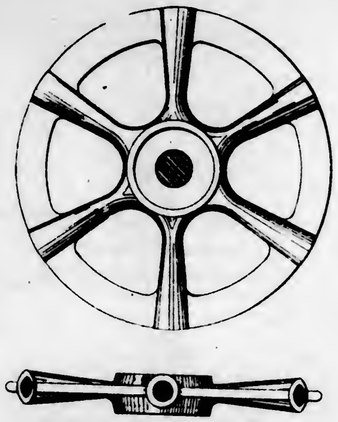
Claim.—The ornamental design for a reflector, as shown and described.

37,809. ILLUMINATOR. OTIS A. MYGATT, New York, N. Y. Filed July 14, 1905. Serial No. 269,734. Term of patent 14 years.



Claim.—The ornamental design for an illuminator, as shown and described.

87,810. STEERING-WHEEL. WILLIAM L. ADAMS, South Portland, Me. Filed Nov. 18, 1905. Serial No. 288,080. Term of patent 7 years.

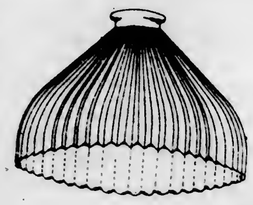


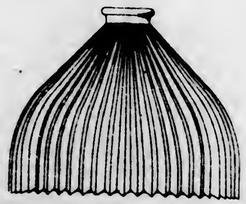
Claim.—The ornamental design for a steering-wheel, as shown.

87,811. CLAY BUILDING-BLOCK. FRANK J. MERKLE, Zanesville, Ohio. Filed Aug. 14, 1905. Serial No. 274,233. Term of patent 14 years.

Claim.—The ornamental design for a clay building-block as shown.

87,812. REFLECTOR OF PRISMATIC GLASS. OTIS A. MYGATT, New York, N. Y. Filed July 15, 1905. Serial No. 269,894. Term of patent 14 years.

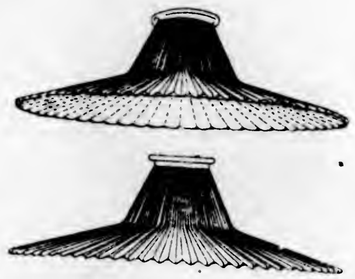




Claim.—The ornamental design for a reflector of prismatic glass, as shown and described.

87,813. REFLECTOR OF PRISMATIC GLASS. OTIS A. MYGATT, New York, N. Y. Filed Aug. 2, 1905. Serial No. 272,443. Term of patent 14 years.

87,813.



Claim.—The ornamental design for a reflector of prismatic glass, as shown and described.

87,814. RUG. ADOLPH PETZOLD, Philadelphia, Pa., assignor to John H. Bromley and Edward Bromley, copartners trading as John Bromley & Sons, Philadelphia, Pa. Filed Dec. 30, 1905. Serial No. 294,023. Term of patent 3½ years.

Claim.—The ornamental design for a rug, as shown.

87,815. RUG. ADOLPH PETZOLD, Philadelphia, Pa., assignor to John H. Bromley and Edward Bromley, copartners trading as John Bromley & Sons, Philadelphia, Pa. Filed Dec. 30, 1905. Serial No. 294,023. Term of patent 3½ years.

Claim.—The ornamental design for a rug, as shown.

87,816. RUG. ADOLPH PETZOLD, Philadelphia, Pa., assignor to John H. Bromley and Edward Bromley, copartners trading as John Bromley & Sons, Philadelphia, Pa. Filed Dec. 30, 1905. Serial No. 294,024. Term of patent 3½ years.

Claim.—The ornamental design for a rug, as shown.

TRADE-MARKS

PUBLISHED FEBRUARY 6, 1906.

The following trade-marks have been adjudged entitled to registration under the act of February 20, 1905, and are published in compliance with section 6 of said act. Said section provides:

"Any person who believes he would be damaged by the registration of a mark may oppose the same by filing notice of opposition, stating the grounds therefor, in the Patent Office within thirty days after the publication of the mark sought to be registered, which said notice of opposition shall be verified by the person filing the same before one of the officers mentioned in section two of this act. If no notice of opposition is filed within said time the Commissioner shall issue a certificate of registration therefor, as hereinafter provided for."

Marks which are stated to have been "Used ten years" are registrable under the last proviso of section 5 of said act, which is as follows:

"And provided further, That nothing herein shall prevent the registration of any mark used by the applicant or his predecessors, or by those from whom title to the mark is derived, in commerce with foreign nations or among the several States, or with Indian tribes, which was in actual and exclusive use as a trade-mark of the applicant or his predecessors from whom he derived title for ten years next preceding the passage of this act."

Section 14 of said act provides for the following fee:

"On filing notice of opposition to the registration of a trade-mark, ten dollars."

SER. No. 246. WHISKY. W. H. JONES AND CO., Boston, Mass. Filed Apr. 3, 1905. Used ten years.

HANOVER

The word "HANOVER."

SER. No. 290. COFFEE. THE H. G. TOMBLER GROCERY CO., Easton, Pa. Filed Apr. 3, 1905.

The words "BLUE KNOT" arranged on a background consisting of the representation of a shield of solid color draped with a ribbon forming a double bow or knot at the top.

SER. No. 416. ALE. THE ROBERT SMITH ALE BREWING COMPANY, Philadelphia, Pa. Filed Apr. 5, 1905.

SER. No. 416.

TIGER HEAD

The fanciful title "TIGER HEAD" and the representation of a tiger's head.

SER. No. 647. CHOCOLATES, BONBONS, AND SIMILAR CANDIES. RUSSELL & CO., Cambridge, Mass. Filed Apr. 6, 1905.

Russell's Original OLD FASHIONED

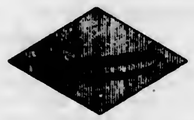
The word "RUSSELL'S" written in script and upwardly inclined, the final "s" having a long wide flourish. An ornamental border surrounds this word consisting of a series of dots and circles, and within the border, following the word "RUSSELL'S," are the words "OLD FASHIONED," while within the upper right-hand corner of said border is the word "ORIGINAL" surmounting a scroll ornament.

SER. No. 899. REMEDIES FOR THE CURE OF BLOOD DISEASES AND RHEUMATISM. CHAS. B. MUNFORD, Kansas City, Mo. Filed Apr. 10, 1905. Used ten years.

SER. No. 899.

The words "MUMFORD'S UNITED STATES NAVY" and a picture representing a sign-board bearing the words and character "UNITED STATES NAVY BLOOD & RHEUMATIC REMEDY." and a man on crutches with one foot bandaged and apparently reading the sign. Diagonally across the picture and the words "UNITED STATES NAVY," above said picture, is printed a facsimile of the signature of the proprietor—viz., "CHAS. B. MUMFORD."

SER. No. 1,046. OVERALLS, COATS, AND TROUSERS. RED DIAMOND CLOTHING CO., St. Louis, Mo. Filed Apr. 10, 1905.



The word "DIAMOND" in script upon a diamond-shaped figure printed in red.

SER. No. 1,115. WATCHES. ELGIN NATIONAL WATCH COMPANY, Elgin and Chicago, Ill. Filed Apr. 11, 1905. Used ten years.

ELGIN WATCH CO.

The words and abbreviation "ELGIN WATCH CO."

SER. No. 1,151. TOOL-STEEL AND STEEL BARS, RODS, AND SHEETS. HAWKRIDGE BROS., Boston, Mass. Filed Apr. 11, 1905.

The pictorial representation of a hawk perched on a ridge with water and distant land in the background.

SER. No. 1,166. FLEXIBLE WATERPROOF FABRIC FOR USE AS ROOFING, DAMP COURSES, AND OTHER PURPOSES. THE STANDARD PAINT COMPANY, New York, N. Y. Filed Apr. 11, 1905. Used ten years.

RUBEROID

The word "RUBEROID."

SER. No. 1,196. BOLA...ES. BRAUN BROS., Baltimore, Md. Filed Apr. 12, 1905. Used ten years.

SER. No. 1,196.

A red disk upon which is printed the words "No. 1 PORTO RICO MOLASSES," associated with the words "WM. M. POWELL & CO. BALTIMORE, MD." arranged in a circle around the aforesaid words, being printed in stenciled letters of plain type.

SER. No. 1,207. BUTTERIN OR OLEOMARGARIN. BRAUN & FITTS, INC., Chicago, Ill. Filed Apr. 12, 1905. Used ten years.

GILT EDGE

The words "GILT EDGE."

SER. No. 1,222. WHISKY. MICHAEL F. MCDONOUGH, Philadelphia, Pa. Filed Apr. 12, 1905.

A player standing by a wicket in the attitude of a bowler, a circle substantially encompassing the player, and a bat on either side of the circle.

SER. No. 1,256. CANNED FRUITS AND VEGETABLES. PRATT-LOW PRESERVING CO., San Jose, Cal. Filed Apr. 12, 1905.

Crossed horizontal and vertical arms, each of red color and having enlarged keystones at opposite ends, and upper and lower segments of a contrasting color extending across the keystones of the vertical arm and having their ends extending to the keystones of the horizontal arm.

SER. No. 1,337. VERTICAL-PLANE CAR-COUPLERS. THE NATIONAL MALLEABLE CASTINGS COMPANY, Cleveland, Ohio. Filed Apr. 13, 1905.

ATLAS

The word "ATLAS."

SER. No. 1,339. VERTICAL-PLANE CAR-COUPLERS. THE NATIONAL MALLEABLE CASTINGS COMPANY, Cleveland, Ohio. Filed Apr. 13, 1905.

CLIMAX

The word "CLIMAX."

SER. No. 1,566. PLAYING-CARDS. THE UNITED STATES PLAYING CARD CO., Cincinnati, Ohio. Filed Apr. 15, 1905.

THE STAGE

The words "THE STAGE."

SER. No. 1,614. WHITE LEAD. WETHERILL & BROTHER, Philadelphia, Pa. Filed Apr. 15, 1905. Used ten years.

The title "EAGLE," the representation of an eagle with outstretched wings, an olive branch in his beak, a torch in one talon, and a spray of leaves in the other talon. Above the representation of the eagle is the representation of a number of stars. Associated with the above are the words "SECOND QUALITY WHITE LEAD WETHERILL & BROTHER, MANUFACT'RS, PHILADELPHIA," and a circular border surrounding the mark.

SER. No. 1,748. CIGARETTES. THE MILLER, DUBRUL & PEYERS MFG. CO., Cincinnati, Ohio. Filed Apr. 15, 1905.

The word "BROWNIE" and the representation of brownies smoking cigarettes arranged on a panel.

SER. No. 1,781. RAZORS. CHALLENGE CUTLERY CORP., Bridgeport, Conn. Filed Apr. 15, 1905.

The word "SPEED," the letters "W. B." with a period after each letter, and the representation of a running hare.

SER. No. 1,929. WHEAT-FLOUR. THE KENNEWEG COMPANY, Cumberland, Md. Filed Apr. 17, 1905.

The word "IVORY," associated with the words "THE KENNEWEG CO. FANCY PATENT CUMBERLAND, MD." and the letters and dots "·X· X· X· X·" and figures "241," all inclosed in an ornamental border.

SER. No. 1,967. BEARING METAL. THE FAIRBANKS CO., New York, N. Y. Filed Apr. 17, 1905. Used ten years.

The arrangement in concentric circles of the words "FAIRBANKS" and "BEARING" arranged between the circles and with the word "METAL" inclosed within the inner circle.

SER. No. 2,020. SALVES. WONDERFUL DREAM SALVE CO., Detroit, Mich. Filed Apr. 17, 1905.

The portrait of Hannah D. McDonald and her facsimile signature, associated with the words "WONDERFUL DREAM" in the arc of a circle following the outline of the circular border, which incloses the whole trade-mark.

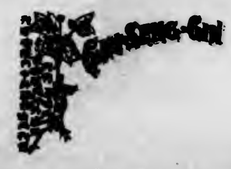
SER. No. 2,101. ELECTRIC BATTERIES. LECLANCHÉ BATTERY CO., New York, N. Y. Filed Apr. 18, 1905. Used ten years.

The representation of a triumphal arch bearing the words "QONDA" and "TRIUMPH OF THE LECLANCHÉ BATTERY CO." and under which is passing a procession, the arch, as well as the banners carried in the procession, bearing also words and clauses descriptive of the goods and their merits, and people viewing said procession.

SER. No. 2,349. REMEDIES, AS TRAS, &c., FOR THE CURE AND ALLEVIATION OF LIVER AND KIDNEY AFFECTIONS, HEADACHE, COUGHS, DIARRHEA, CHOLERA, CHILLS AND FEVER, LA GRIPPE, AND CONSTIPATION. HENRY A. BLAIR, San Antonio, Tex. Filed Apr. 21, 1905.

The words "MOTHER SUPERIOR," associated with the fanciful portrait of a woman wearing the conventional garb of a Mother Superior. At one side of the mark is arranged a vertical strip of red and at the other side a vertical strip of green.

SER. No. 2,602. LIQUID MEDICINE TO BE TAKEN INTERNALLY AS A CURE FOR ORGANIC AND NERVOUS DISEASES. THE GIN-SENG-GIN COMPANY, Cincinnati, Ohio. Filed Apr. 21, 1905.



The picture of the root, stalk, and flower of a plant, and simulations of Chinese characters, accompanied by the hyphenated syllables "GIN-SENG-GIN."

DECISIONS

OF THE

COMMISSIONER OF PATENTS

AND OF

UNITED STATES COURTS IN PATENT CASES.

COMMISSIONER'S DECISIONS.

POTTER v. MCINTOSH.

Decided January 12, 1906.

1. INTERFERENCE—APPEAL ON PRIORITY—CONSIDERATION OF PATENTABILITY.

Where a party who cannot prevail upon priority takes an appeal from the decision against him thereon merely for the purpose of attacking the patentability of the issue, *Held* that the appeal raises merely the question of priority, and the decision below must ordinarily be affirmed without consideration of the question of patentability, for the reasons given in *Sobey* v. *Holsclaw*, (119 O. G., 1922.)

2. SAME—SAME—SAME.

Whatever objections there may be to the policy and rule preventing appeal from decisions affirming patentability or right to make claims in those cases where affirmance may result in preventing the issue of a patent to a party who, in the event of a contrary decision, might have been entitled thereto, this policy and rule are believed to be in accordance with sound reason and unimpeachable in their application to cases where the would-be appellant upon patentability has in any event no standing before the Office as a claimant for a patent upon the matter in question.

3. SAME—SAME—SAME—STATEMENT OF EXAMINERS-IN-CHIEF.

Where in their decision on priority one Examiner-in-Chief found the issue to be patentable and another found it unpatentable and the third was absent. *Held* that the case is not distinguished in substance from one where all three found the issue unpatentable, since by their divided opinion they affirm the conclusion of the Primary Examiner that the issue is patentable.

APPEAL from Examiners-in-Chief.

EMERGENCY-BRAKES.

Mr. Albert G. Davis for Potter. (*Mr. Arthur A. Buck* of counsel.)

Mr. Charles H. Roberts for McIntosh.

ALLEN, *Commissioner:*

This is an appeal by Potter from the decision of the Examiners-in-Chief awarding priority of invention to McIntosh.

In this case the appellant failed to allege in his preliminary statement dates of invention early enough to overcome the record date of his opponent and brings this appeal for the sole purpose of attacking the patentability of the issue and preventing the grant of a patent to his opponent for the invention defined therein. An appeal of this kind was brought and disposed of in the case of *Sobey* v. *Holsclaw*, (119 O. G., 1922.)

It was pointed out there that upon such appeal as the present the case is before me simply upon the question of the priority of the parties with regard to the subject-matter of the issue and that the junior party having conceded in his preliminary statement that he was subsequent to his opponent in the possession of this matter there is nothing for me to do but to affirm the decision of the Examiners-in-Chief in favor of the senior party. I am convinced that Potter should not be heard upon this appeal in opposition to the grant of a patent to McIntosh on the ground that the issue is not patentable. The reasons for this conclusion were set forth fully in *Sobey* v. *Holsclaw*, *supra*, and need not be repeated here.

The circumstances of the present case do not appear to be distinguished from those of that case except in regard to the matter of recommendation by the Examiners-in-Chief under Rule 126. In the former case the Examiners-in-Chief after considering the arguments upon patentability refused to include in their decision upon priority a statement that in their opinion the issue was not patentable. In the present case one Examiner-in-Chief found the issue to be patentable and another found that it was not patentable, and they so stated. The third was absent. This distinction between the cases is not one of consequence. In this case the Primary Examiner has twice found the issue to be patentable, the second time upon *inter partes* consideration on the motion by Potter for dissolution. Under established policy, expressed in Rule 124, parties are denied the right of appeal from decisions affirming the patentability of claims. In spite of this policy and rule Potter has, in effect, had the benefit of an appeal to the Examiners-in-Chief, who by their divided opinion failed to disturb the conclusion of the Primary Examiner that the issue is patentable. No reason is seen for permitting Potter to continue this course of irregular appeal. Whatever objections there may be to the policy and rule preventing appeal from decisions affirming patentability or right to make claims in those cases where affirmance may result in preventing the issue of a patent to a party who, in the event of a contrary decision, might have been entitled thereto, this policy and rule are believed to be in accordance with sound reason and unimpeachable in their application to cases like the present, where the would-be appellant upon patentability has in any event no standing before the Office as a claimant for a patent upon the matter in question.

In this case, as in *Sobey* v. *Holsclaw*, counsel for appellant requests that it appear in this decision that I refused him permission to argue upon the patentability of the issue at the hearing upon this appeal. He was so refused, for the reasons given herein and in the decision in the case referred to.

The decision of the Examiners-in-Chief affirming the decision of the Examiner of Interferences awarding priority of invention to McIntosh is affirmed.

DECISIONS OF THE U. S. COURTS.

Court of Appeals of the District of Columbia.

BAUER *v.* CRONE.

Decided December 5, 1905.

INTERFERENCE—PRIORITY.

Held that the controversy turned entirely upon the facts in evidence; that in addition to the burden imposed upon him by the patents regularly issued to Crone, Bauer has that of overcoming the effect of the successive adverse decisions in the Patent Office; that the evidence on behalf of Bauer is uncertain, fraught with suspicion, and cannot be accepted as sufficient proof of the facts essential to establish the appellant's averments either as originally made or as sought to be amended, and that the decision of the Commissioner must be affirmed.

Mr. F. W. H. Clay and *Mr. Melville Church* for the appellant.

Mr. Chas. C. Gill and *Mr. Wm. G. Henderson* for the appellee.

SHEPARD, *J.*:

The invention in controversy in this proceeding is defined in the following issue in three counts:

1. A brake-beam fulcrum in one integral piece of forged metal folded about its center and forming the angularly-disposed sides and at its ends having flanges, said sides being connected at their outer ends only, substantially as described.
2. A forged-metal brake-beam fulcrum comprising the angularly-disposed side members having at their inner ends flanges, said side members having at their inner ends laterally reversely offset end portions for the formation of said flanges, combined with means connecting said members adjacent to said flanges, and said members beyond their connecting means being apertured to receive the bolt for the brake-lever, substantially as described.
3. A forged-metal brake-beam fulcrum comprising the angularly-disposed sides having at their inner ends reverse offsets forming flanges, and means for connecting said sides to the body-beam, said offsets permitting without materially stretching the metal, the formation of said flanges and the setting of said sides into their angular positions, substantially as set forth.

The appellee, Seth A. Crone, claims under three patents. Count 1 of the issue corresponds to a claim in the first of these, No. 720,676, issued February 17, 1903; count 2 corresponds to a claim in the second, No. 731,668, issued June 23, 1903; count 3 corresponds to a claim in the third, No. 731,865, granted June 23, 1903. Bauer's application embracing each of the counts was filed October 14, 1903. In his preliminary statement, he alleged conception of the invention, on or about June 1, 1900; production of sketches and drawings on or about June 27, 1900, showing count 1, and showing counts 2 and 3 on or about September 3, 1902; disclosure to others of count 1 about June 27, 1900, and of counts 2 and 3 about September 3, 1902; construction of full-size models of all, and reduction to practice on or about November 10, 1902. He also alleged that since said last date he has had at least five thousand or ten thousand of the described fulcrums made and used. About the time that the taking of testimony was begun, Bauer moved to amend his preliminary statement by setting back the date of making drawings and disclosures of the invention comprised in counts 2 and 3 from September 3, 1902, to August 15, 1902, and his date of reduction to practice from November 10, to October 1, 1902. This amendment was denied. The Examiner of Interferences, and the Examiners-in-Chief on appeal to them, decided in favor of Crone upon all three counts. Bauer then appealed to the Commissioner, but on the hearing abandoned his appeal as to count 1. The Commissioner affirmed the decision of the Examiners-in-Chief, and Bauer has prosecuted his appeal therefrom as to counts 2 and 3.

The controversy turned entirely upon the facts in evidence, and in addition to the burden imposed upon him by the patents regularly issued to Crone, Bauer has that of overcoming the effect of the successive adverse decisions in the Patent Office.

The evidence on behalf of Bauer has been fully and fairly reviewed in each of the decisions referred to, and we could add nothing material thereto by further discussion. We agree fully with them that this evidence is uncertain, fraught with suspicion, and cannot be accepted as sufficient proof of the facts essential to establish the appellant's averments either as originally made or as sought to be amended.

The decision must be affirmed. It is so ordered, and that the proceedings herein be certified to the Commissioner of Patents in accordance with the requirements of the law. Affirmed.

Court of Appeals of the District of Columbia.

FRENCH *v.* HALCOMB.

Decided December 5, 1905.

1. INTERFERENCE—ORIGINALITY.

Evidence considered and *Held* insufficient to clearly prove that the invention of the issue originated with French rather than Halcomb.

2. SAME—BURDEN OF PROOF—APPLICANT *v.* PATENTEE.

An applicant in interference with a patent granted before the filing of the application has the burden of proving his case beyond a reasonable doubt, and this burden is not discharged where the testimony merely raises a doubt as to which of the two parties made the invention or whether a third party may not have contributed the essential idea which led to the invention.

3. SAME—EVIDENCE OF INVENTOR PRACTICALLY UNCORROBORATED.

The statements in a memorandum of a note-book produced by French, one of the interfering parties, and alleged to disclose the invention in issue *Held* insufficient to prove conception where it appears that the entry was seen by no one and there is no corroborative evidence on the point except a statement of another witness that French produced such a book at a given date.

Mr. Geo. H. Christy and *Mr. M. A. Christy* for the appellant.

Mr. Alfred Wilkinson for the appellee.

SHEPARD, *J.*:

This is an interference proceeding involving the invention of high-grade steel as described in the following three counts of the issue of interference:

1. A high-grade steel containing less than 1.20 per cent. of carbon, and from six per cent. to fifteen per cent. of molybdenum.
2. A high-grade steel containing less than 1.20 per cent. of carbon, from six per cent. to fifteen per cent. of molybdenum and from 2.50 per cent. to six per cent. of chromium.
3. A high-grade steel containing less than 1.20 per cent. of carbon, from six per cent. to fifteen per cent. of molybdenum, from 2.50 per cent. to six per cent. of chromium and less than two per cent. of silicon.

The junior party, Edmund L. French filed his application May 6, 1903. His preliminary statement alleges conception about December 31, 1899, disclosure on the same date, and reduction to practice on or about April 24, 1902.

Halcomb's claim is founded on a patent issued March 10, 1903, upon an application filed January 21, 1903. No preliminary statement by him is found in the record, and he has taken no testimony. His date of conception and constructive reduction to practice are fixed by his application.

Upon the evidence taken by French in support of his claim, the Examiner of Interferences awarded priority to

Halcomb. This decision was reversed by the Examiners-in-Chief. They, in turn, were reversed by the Commissioner who decided in favor of Halcomb.

Having filed his application after the patent had been issued to Halcomb, French is charged with the burden of establishing his prior right beyond a reasonable doubt.

The several decisions of the Patent Office tribunals show that the points at issue have received very careful consideration, and those of the Examiner of Interferences and the Commissioner review the testimony at length.

Both parties are deeply skilled in the art of manufacturing high-grade steel particularly adapted for making tools used in working steel, and capable of operation at high speed. Halcomb was formerly the president of the Sanderson works at Syracuse, N. Y. In July, 1900, that plant was taken over with many others by a new organization called The Crucible Steel Company of America, of which Halcomb then became president, holding the office until June, 1902. Before this date, the invention of the issue was reduced to practice at the Sanderson works.

In 1897, French, who was then twenty-seven years of age, was employed as a chemist by the Sanderson Company. Subsequently, as stated by him, he had—

charge of the formulæ for making steel and general charge of the metallurgical end of the business there.

While Halcomb was president of the Sanderson company he had constant direction and supervision of all the analyses made and experiments tried. After removal to Pittsburg as president of the general owning corporation, he frequently visited the Sanderson works, and through reports and letters from French was advised of all that took place there until the relinquishment of his last position in June, 1902. During the whole period there was constant competition with high-speed tool-steels of foreign manufacture. It appears from the testimony of French, that, before 1898, or 1899, molybdenum had not been used to any extent as an ingredient of tool-steel, and that after experiments therewith at the Sanderson works, it was decided in November, 1900, to substitute it for the tungsten grade, then in general use. In the meantime, or shortly after, the Crucible Steel Company acquired a practical monopoly of molybdenum in the United States.

The record sets forth lengthy correspondence between French and Halcomb, relating to many analyses of steel, the product of different manufacturers, specimens of which were generally sent by Halcomb for the purpose, and to experiments carried on by French chiefly, at least, under Halcomb's instructions. This began September 24, 1901, and ended May 3, 1902. In this first letter from Halcomb to French, dated September 24, 1901, he said:

I don't want any experimental steels to be made at Syracuse or elsewhere without my previous knowledge and sanction, nor must any change be made either in the mixtures.

The testimony in general shows not only that the advantages of the use of molybdenum instead of tungsten were recognised fully, but that low-carbon mixtures were already in general use. It seems, also, that the suggestion of a combination of very low carbon with molybdenum came from one B. V. Maxwell, also an expert employee of the Crucible Co. Writing to Halcomb, under date of January 12, 1902, he refers to a new steel, which he says is a "wonder," of the following composition: 11½ per cent. tungsten, 2½ per cent. chromium and eight-tenths of 1 per cent. carbon. He then suggests that the Sanderson works—get out for experiment, a few pieces for test of a very low carbon, molybdenum self-hardenings teel.

Prior to that, as shown by French's letter of December 6, 1901, he had made an analysis of a sample of Capital steel, manufactured by others, which had been sent by Maxwell. This shows a composition of tungsten, chromium, silicon and forty-one one-hundredths of carbon. In concluding this letter to Halcomb he says:

There is not a steel in existence that can stand long against our Mo. steel treated, and as long as we can keep a fair control over the molybdenum market, we can laugh at competition in the steel-hardening line.

It would protract this opinion to an unusual length to undertake to review all of this correspondence, nor is it important to do so.

Counsel for French refer especially to his letter to Halcomb of March 14, 1902, as first disclosing this invention among the experimental analyses therein given. The Commissioner expressed the opinion in his decision that French's suggested composition was nothing more than the report of the result of Halcomb's directions in his letter of January 14, and March 1, 1902. The first of these directs a sample made according to the analysis of the "Capital" steel, hereinabove mentioned, for test by Maxwell. Attention is also called to what Maxwell had said about the composition of another steel—the "wonder" described in Maxwell's letter of January 12—and concludes:

This latter we could easily duplicate, but I also think that molybdenum can be substituted for tungsten to advantage.

In this letter he refers to samples of steels sent to French and gives analyses that had been made at other works belonging to the Crucible Co. Two of these showed tungsten, by substituting molybdenum for which, according to the well-known proportion of about one for two, as indicated in former letters to French, the composition of the issue was substantially disclosed. Moreover, he adds:

I would like you to get more information for me on those steels. Make some tests with them and see how you think they are as compared with our S. H. Mo. specially treated, and whether you think there is anything in having the carbon lower.

It is not necessary for the purposes of this case to consider whether Maxwell may not have contributed the idea which led directly to the specific composition that has been declared patentable, or whether Halcomb had a substantial conception of the same when he gave his directions to French to make experiments upon that line. Nor need we determine that what French may have come upon in carrying out the directions of Halcomb accrued to the latter as his employer for that purpose. It is sufficient only to say that all of the testimony taken together has no greater effect than to raise a doubt merely as to whether French or Halcomb had the first conception of the invention. The raising of such a doubt, however, does not meet the requirement of the burden imposed by the established rule upon one who seeks to overcome a regularly-issued patent.

A part of the testimony, considered in reaching the foregoing conclusion, consists of a long memorandum in a note-book produced by French. This memorandum, bearing date September 14, 1900, is too lengthy to be recited. Assuming that it discloses the "low-carbon idea" completely, the proof of it is insufficient. French kept this book to himself. No one read the entry. One witness testifies that French produced a book like this in May, 1902. He gives no precise date, but any time in May was more than a month after the letters passed between French and

Halcomb, that have been particularly referred to above. Moreover, the witness's recollection of what he heard is rather indefinite. The practically uncorroborated evidence of the inventor himself cannot be accepted as proof of conception. (*Winslow* v. *Austin*, 14 App. D. C., 141; *Garrells* v. *Freeman*, 21 App. D. C., 207, 212.)

Again, there are some circumstances tending to cast doubt upon the actual date of this memorandum. Throughout French's entire correspondence with Halcomb, there is no reference to it. In a letter written December 16, 1902, to Halcomb's successor as president of the Crucible Co., he refers to an idea he had had for securing patents for the company's benefit upon all mixtures then in use. The particular composition is not mentioned, save as it may be included in all the mixtures of molybdenum, and he goes on to say:

> I believe we should take out patents covering the use of molybdenum alone for high-speed steels, and for all high percentages of molybdenum and chromium, also patents for low percentages of the same, such as might be used in magnet and other special steels.

No applications seem to have been prepared, certainly none were filed, until after Halcomb's patent had been brought to his attention. He refers to this in a letter to Smith of March 31, 1903. Making no statement of his own invention, he says:

> I regret that my delay in giving you the specifications as required by our patents attorneys has perhaps allowed Mr. Halcomb to step in first and secure rights, and am sorry now I took so much pains to have the claims broad. The patent I had in mind would have covered a wider field than Halcomb's in case the magnet-steels had proven a success.

After some further correspondence between the same parties, relating to patent applications, French wrote on April 28, 1903, for his letters to Halcomb of March 28, 29, April 5 and 6, 1902, saying:

> These letters should show whether Mr. Halcomb instructed me, as his own idea, to duplicate the various high-speed steels of which I sent him an analysis, or whether I made the suggestion that it be done and get his approval.

This is followed by those analyses, seven in number, that were given in the correspondence with Halcomb. The letter then proceeds as follows:

> These were duplicated here by making molybdenum steels with one-half the percentage they contained in tungsten, approximately, and were given the numbers at the left of the table above, which you will find to correspond with the table of experimental steels already in your hands. I think the letters I have mentioned above as missing will supply the information we want as to the originality of the idea, if there was any. It seems to me that it will be best to work on the fact that what was done by the Sanderson Bros. Steel Co. while Mr. Halcomb was here, and afterward while he was president of the Crucible Steel Co., was not original with him or with me, but was merely imitation of what had already been accomplished with molybdenum by others. I find that we made an analysis of Crescent Mo. self-hardening here before we ever made it ourselves. A sample of Crescent Mo. steel analyzed April 1, 1900, showed C. 1.65, Mo. 3.98, Cr. 4.22, and it is probable that the ingot made at the Sanderson works April 18, 1899, was a copy of this, the analysis being so similar, namely, C. 1.60, Mo. 4.03, Cr. 4.02. Mr. Halcomb added .64 silicon to this analysis on general principles, it being our practice at that time to use about that amount of silicon in our tungsten self-hardening steel.
>
> In the same way that we copied the Crescent steel for high-carbon self-hardening, we imitated the various makes of foreign low-carbon steel, and Mr. Halcomb says to me in a letter dated March 31, 1902: "It is quite evident now that every one is working on low carbons, and that is what we have got to do."

This was written on receipt of the list of analyses quoted in the first part of this letter. Mr. Halcomb says further in his letter of the 31st March:

> I think that Krupp's would be a very good steel to duplicate, with, say, .75 carbon, 9.75 tungsten, or half that quantity Mo., 3.00 chromium, .25 to .35 silicon. There is not a great deal of difference, I should think, between that and Vickers-Maxim, though for the latter add a little more chromium and use a little less tungsten. Suppose you make an ingot of each, one being of the analysis I have just given you and the other like Vickers-Maxim, .78 carbon, 7.35 tungsten, or one-half the amount of Mo., and 3.75 chromium. Then we will find out which is the better of the two. The Styrian steel must be a great deal more expensive than either of the others. Still it would be interesting to know what results could be obtained with about .60 carbon, 10.00 Mo. and 6.50 Cr.
>
> I believe you will find that in my letter of March 28 to Mr. Halcomb, or that of March 29, I suggested to him that we duplicate all the foreign steels, analysis of which I gave him and contained in the table on the first page of this letter.
>
> I am certain that he never gave me any suggestions or instructions as to the analysis of steel No. 5 or No. 9, both of which proved superior to any of the others, and both of which have been used as our regular steels.
>
> I send inclosed a copy of matter in my note-book under date of September 14, 1900, which will show that I had the low-carbon idea long before it was used in this country or abroad, and that I told Mr. Halcomb about it. I never made the experiments spoken of in my notes, being discouraged from trying them at that time by Mr. Halcomb's opposition, he having no faith in what I proposed.

It is singular, to say the least, that one now claiming the invention, and with his note-book and the correspondence before him, should have suggested a doubt whether it was original with him or Halcomb either, and also whether it was an invention at all because an imitation of what had already been accomplished by others. Although he sent the memorandum of the note-book for the consideration of the patent experts of his company, it seems that the only thing he then claimed as original was the "low-carbon idea."

It does not appear when the low-carbon steels of foreign manufacture, which French analyzed in 1901 and 1902, were first made, but the "low-carbon idea" was certainly not a new one in 1900, because French's witness, Gardner, who was manager of the Sanderson works, said that low-carbon self-hardening steels had been made years ago by two different English manufacturers, and that he had formerly been in the service of one of them as assistant manager of the rolling-mills.

We are far from being convinced that French was the first to conceive the specific invention of the issue, and must, therefore, affirm the decision of the Commissioner. It is so ordered, and that this decision be certified to the Commissioner of Patents as the law requires. Affirmed.

Court of Appeals of the District of Columbia.

GILES REMEDY COMPANY v. GILES.

Decided December 12 1905.

1. TRADE-MARKS — APPEAL TO COURT — INTERFERENCE DECLARED UNDER ACT OF 1881.

   A trade-mark interference declared under the act of 1881, but not decided until after the passage of the act of February 20, 1905, is appealable to the Court of Appeals of the District of Columbia under the act of February 20, 1905, where the only application involved has been amended to bring it under the provisions of that act.

2. SAME—SAME—PENDING APPLICATION.

   A trade-mark application which was involved in an interference at the time of the passage of the act of February 20, 1905, was a pending application such as might be amended to bring it under the act.

3. SAME—INTERFERENCE—PRIORITY OF ADOPTION AND USE.

   Where it appears that Sanford Giles first adopted and used the trade-mark and secured registration thereof and subsequently the mark was used by him and by Daniel Giles at a single place of business under the name of the Giles Remedy Company until a disagreement between them which resulted in their separation, *Held* that Sanford Giles was the owner of the mark and that judgment of priority must be in his favor.

4. SAME—SAME—SAME—RIGHT ACQUIRED BY TRANSFER.

   Where a trade-mark registrant is shown to have been the first to adopt and use the mark and to have been the owner at the time he secured the registration, he is not to be defeated in an interference by showing that his opponent subsequently acquired title to the mark from him. Such showing might in appropriate proceedings justify compelling the transfer of the certificate of registration; but it does not justify the holding that the later applicant was the first to adopt and use the mark.

5. SAME—OWNERSHIP BY PARTNERS—RIGHTS UPON DISSOLUTION.

   The general rule that when a partner retires from a partnership and assents to the retention by the other partners of the possession of the old place of business and the future conduct of the business by them under the old name the trade-mark remains with the latter has no application to the facts of this case.

6. SAME—SAME—SAME—WITHDRAWAL OF MEMBER.

   In the absence of express agreement a trade-mark used theretofore by one who enters into partnership with others does not at the dissolution of the partnership, caused by the withdrawal of the member bringing the mark into the partnership, remain the property of the partnership.

Mr. W. H. Chamberlin and *Mr. Geo. L. Wilkinson* for the appellant.

Mr. W. C. Jones and *Mr. Geo. R. Hamlin* for the appellee.

DUELL, *J.*:

Preliminary to a decision as to the correctness of the finding of the Commissioner of Patents that priority of adoption and use of the trade-mark in issue was by the appellee, Sanford F. Giles, we are called upon to determine whether this is a case where an appeal lies to this court, a motion having been made to dismiss the appeal on the ground that this court is without jurisdiction to entertain the appeal. The material facts disclosed by the record will be briefly stated. Under the law of 1881 a certificate of registration of the trade-mark in controversy was granted to Sanford F. Giles on June 29, 1897. The Giles Remedy Company, a corporation of the State of Illinois, on September 15, 1904, made application for substantially the same trade-mark, and an interference on October 11, 1904, was declared between Sanford F. Giles, the registrant, and the application of the Giles Remedy Company. Both parties took proofs, and on the proofs and proceedings a hearing was had before the Examiner of Interferences who, on March 11, 1905, found in favor of the registrant, Sanford F. Giles. Limit of appeal was fixed to expire March 31, 1905, and on that date an appeal to the Commissioner was duly taken. The decision of the Examiner of Interferences was affirmed by the Commissioner on June 29, 1905. Under the law of 1881 an appeal did not lie to this court in interferences relating to trade-marks. Such appeal was provided for by the law of 1905 which went into effect April 1, 1905. Section 24 of that law made the following provision for pending trade-mark cases:

> Sec. 24. That all applications for registration pending in the office of the Commissioner of Patents at the time of the passage of this act may be amended with a view to bringing them, and the certificates issued upon such applications, under its provisions, and the prosecution of such applications may be proceeded with under the provisions of this act.

The appellant, being an applicant, on the 6th of April, 1905, filed its petition asking to amend the application involved in this proceeding to bring it within the provisions of the act, and this petition was received and approved by the Patent Office.

We do not see how the Patent Office could have lawfully refused the petition, for the application of the Giles Remedy Company for registration of its claimed trade-mark was pending in the office of the Commissioner of Patents at the time of the passage of the act. While the act did not take effect until April 1, 1905, it was passed—that is approved—February 20, 1905. On that date the Examiner of Interferences had not filed any decision, and of course no appeal had been taken to the Commissioner of Patents. At the April, 1905, term of this court we reviewed at length the question as to what was a pending application for registration of a trade-mark as that term was used in the act of 1905, and under our ruling in that case, to which reference is made, without again stating our conclusions and the reasons therefor, the application of the Giles Remedy Company, appellant, is clearly a "pending" application and was such not only on the 20th of February, 1905, when the act was approved, but also on April 1, 1905, when it went into effect. Section 7 of the act provides for the declaration of an interference between a registered mark and an application for the registration of a conflicting mark and section 9 provides for an appeal in such interferences to this court. Appellant is rightfully in this court, and the motion to dismiss his appeal must accordingly be denied.

This brings us to the consideration of the merits of the appeal. The facts, so far as they are material to the decision of any questions which are properly before us in this proceeding, are substantially these.

Daniel S. Giles, Sr., through whom the Giles Remedy Company, appellant, became vested with any claim of title it may have to the trade-mark in question, undoubtedly originated the medicine in connection with which the trade-mark is used, and disposed of it by gift or sale, in small quantities for years before Sanford F. Giles put the medicine on the market. Both father and son sold the medicine before the trade-mark came into being. It is equally well proven that Sanford F. Giles originated the trade-mark, and in September, 1894, caused labels for bottles, and also other printed matter, to be printed by a printing establishment located at Kansas City. These labels had on them a seal with serrated edges and upon the seal the words "Giles Magic Lotion." At that time he lived at Pleasanthill, Mo., and was by occupation a telegraph operator. For a year or more prior to September, 1894, he had sold the medicine, probably using the trade-mark, and had put it out under the name of the Giles Remedy Company. He was undoubtedly the first to use that tradename. In 1896 he removed to Kansas City, and for a time lived with his father, both engaged in putting the medicine on the market in a happy-go-lucky sort of a way. There was no partnership, at least at the commencement of their relations, and, so long as they continued to live at Kansas City, it can hardly be said that this record discloses that their relations amounted in law to a partnership relation. A bank account was kept by Sanford but that does not prove that the business carried on was his, nor does it tend to prove a partnership. From an examination of the testimony we conclude that each sold what he could and used the proceeds as he pleased; that each sought to make a living out of the business, and as long as one had enough for that object he cared little what amount of money the other made out of the business. It was a relation that was quite natural between a father and son whose feelings for each were natural, and such as often exists between father and son. The business at first was small, and each worked in an independent sort of a way, and each in his own way sought to increase the business. We fail to discover sufficient to warrant us in a conclusion that in the spring of 1897, when Sanford executed and filed the application for registration of the trade-mark, he had divested himself of the right to file the application in his own name so that a trade-mark could be lawfully issued to him upon his own application. No doubt his father thought, and had a right to think, that the trade-mark was to be used by him as well as by Sanford. But the latter having been the first to adopt and use the trade-mark, and not having parted with his interest in it, and having continued its use, had not by acquiescing in its use by his father in the manner shown forfeited his right to claim the mark as his own property. Conceding that his father furnished the money used in procuring the trade-mark, we cannot, in view of the loose way in which the business was carried on, infer or find from that fact that a partnership existed between them. It was in fact at that time the same as though two peddlers living under the same roof, made up their packs without paying much attention to who paid the most for the goods they sold, or what became of the proceeds so long as one if he had more money than he needed would lend it to the other.

It was a very natural relation, under the circumstances, to exist. We hardly think that the father's right to use the mark had in the spring of 1897 ripened into a legal right that he could then have enforced. Undoubtedly as the years passed and the business increased, and books were kept and a bank account was kept in the name of the Giles Remedy Company (a trade-name devised by Sanford F. Giles) against which both could check, there developed a more business-like relation. But as we look at the question we are called upon to decide, any finding we might make as to the later relations between the father and son, and their several relations to the business, would be of no moment. Another forum is provided for the determination of those questions. If Sanford F. Giles was the first to adopt and use the trade-mark in question, and not having ceased to use, or not having parted with the legal title to register the mark when he did—all which we have found—it would be a vain thing for us to find that after the registration he had parted with an interest, or any part, of the exclusive right to use the mark. The title to the certificate of registration, if claimed under some act or set of acts done or performed after its issue, cannot as a rule be determined in an interference proceeding. Such question is, we apprehend, to be tried in a proceeding brought to compel the assignment of the issued certificate, or by some analogous proceeding. There may hereafter be found some exception to the general rule, but this is not one and we have now none in mind. An interference proceeding under the trade-mark law is instituted to determine priority of adoption and use, and when it is found that one of the parties to the interference was the first to adopt and use the mark in accordance with the requirements of the law, and was the sole owner of the mark when he applied for and received the certificate of registration the inquiry instituted by the interference proceedings terminates. If a later applicant seeks to re-register the mark for any lawful reason, and it appears that his title is based upon the same adoption and use as claimed by the prior registrant it cannot be successfully contended that he has any standing in an interference unless, at least, he shows that the entire right, title and interest in the mark has become vested in him. Appellant has failed to show this, for any right vested in the corporation, appellant, is such title as Daniel S. Giles, Sr., had in the mark when he attempted to assign all interest in the mark to it and caused the application for registration to be filed in its name. Daniel S. Giles, Sr., is not shown to have had at any time such title as would have permitted him to register the mark. He did not originate it nor first put it in use. Nothing, so far as this record discloses, vested in him at any time the exclusive right to its use. That after its registration by Sanford F. Giles he acquired some rights we think the record discloses. At the best those rights are not shown to be exclusive or to warrant a judgment of priority in his favor. The partnership, if it be admitted that a partnership existed between father and son, did not vest him with the exclusive right to the mark; and when the relation was terminated by the father's annexing the bank account, and the departure of the son from the common place of business, the condition that then arose did not in law vest the father with all rights to the mark on the ground that the son had abandoned his rights.

The propositions of law advanced by the appellee are well founded and sustained by many adjudicated cases. Briefly summed up they are that registration of a trade-mark is grantable only to its owner, and such owner is the one first to adopt and use the mark as provided by law. The Trade-Mark Acts of 1881 and 1905, and the adjudications under the former act all sustain the proposition. That the right to use a trade-mark owned by a partnership—after its dissolution, generally is vested in all of the members who continue in the same line of trade. (*Menendez* v. *Holt*, 128 U. S., 514.) That in the absence of an express agreement, a trade-mark used theretofore by one who enters the partnership does not at the dissolution of the partnership, caused by the withdrawal of the member bringing the mark into the partnership, remain the property of the partnership. (*Am. & Eng. Encyc. of Law*, 2nd Ed., Vol. 28, p. 406, and cases there cited.)

It is undoubtedly true as urged by appellant that when a partner retires from a partnership and assents to the retention by the other partners of the possession of the old place of business and the future conduct of the business by them under the old name that the trade-mark remains with the latter. The facts in the present case do not warrant the application of that rule of law for the retirement must be voluntary, or thereafter acquiesced in, and the retention of the business must have also been acquiesced in and not practically forced.

It appears that the parties to this interference are engaged in a litigation pending in the courts of the State of Illinois, and their respective rights to the registered trade-mark can there be determined. As before stated we have no call to determine that question having found that Sanford F. Giles lawfully registered the mark in controversy and that the appellant has failed to show that after such registration it became the sole owner of the registered mark and of all rights thereto pertaining.

In our opinion the Commissioner of Patents was right in awarding judgment of priority of adoption and use of the trade-mark to the appellee, Sanford F. Giles, and his decision should therefore be affirmed. The clerk of the court will certify this opinion, and the proceedings in this court in the premises, to the Commissioner of Patents, according to law. Affirmed.

Notice.

DEPARTMENT OF THE INTERIOR,
UNITED STATES PATENT OFFICE,
Washington, D. C., February 2, 1906.

The following assignment from The Pennsylvania Railroad Company dedicating to the public the invention secured by United States Letters Patent No. 790,690, granted May 23, 1905, to William F. Kiesel, Jr., for improvements in tank-cars has been recorded in the assignment records of this Office and is published for the information of the public.

F. I. ALLEN,
Commissioner.

Whereas Letters Patent of the United States were granted May 23, 1905, to William F. Kiesel, Jr., of Altoona, Pa., numbered 790,690, for improvements in tank-cars; and

Whereas The Pennsylvania Railroad Company, a corporation of the State of Pennsylvania, whose principal office and place of business is in the city of Philadelphia, in said State, by virtue of an assignment from said William F. Kiesel, Jr., dated November 5, 1904, and recorded in the United States Patent Office November 17, 1904, in Liber T-70, page 250, of the Transfers of Patents, is now the sole owner of said Letters Patent, and of all right, title and interest therein, and of the invention covered thereby; and

Whereas the said The Pennsylvania Railroad Company is desirous that the invention described and claimed in and by said Letters Patent may be freely made and used within the United States and its Territories and without compensation to said company:

Now therefore this indenture witnesseth: that the said The Pennsylvania Railroad Company does hereby grant to the public of the United States, and to each and every member thereof, including persons, firms and corporations, the right to make, to make and use, to use, and to vent to others to be used, the said invention described and claimed in and by said Letters Patent numbered 790,690, granted May 23, 1905, to said William F. Kiesel, Jr., as aforesaid, the same being an improvement in tank-cars, without any liability under said Letters Patent to said The Pennsylvania Railroad Company, or to its successors or assigns, the said right so granted to continue during the full term for which said Letters Patent are or may be granted and to extend to any reissues, renewals or extensions thereof.

But nothing herein contained shall be construed as an assertion or as an acknowledgment by the said The Pennsylvania Railroad Company of the validity of the said Letters Patent numbered 790,690, or of any reissue or extension thereof, or as an assumption by said The Pennsylvania Railroad Company of any liability which may now or hereafter be incurred by any one in the manufacture, sale, or use of the invention covered by said Letters Patent, growing out of the infringement of any other patent or patents.

In witness whereof the said The Pennsylvania Railroad Company has caused these presents to be signed by its vice-president and its corporate seal to be hereto affixed this tenth day of January, A. D. 1906.

[L. S.] THE PENNSYLVANIA RAILROAD COMPANY,
By SAMUEL REA,
Vice-President.

Attest:
LEWIS NEILSON,
Secretary.

Printed Copies of Patents.

A printed copy of the complete specification and drawings of any patent published herein can be obtained for five cents.

Trade-Marks.

The publication of trade-marks under the act of February 20, 1905, in the OFFICIAL GAZETTE, commenced May 2, 1905, and will appear in each weekly number of the GAZETTE thereafter.

Extra copies of the trade-mark portion of the GAZETTE, which will be sold separately, may be obtained single or in quantities for five cents each. Coupons will be taken in payment therefor.

Interference Notice.

DEPARTMENT OF THE INTERIOR,
UNITED STATES PATENT OFFICE,
Washington, D. C., February 7, 1906.

John H. Thompson & Company, their assigns or legal representatives, take notice:

An interference having been declared by this Office between the application of Charles H. Montanye, of New York, N. Y., for registration of a trade-mark and a trade-mark registered to John H. Thompson & Company, of Detroit, Mich., and the notice of said declaration mailed by the Patent Office in the usual manner to the said John H. Thompson & Company having been returned undelivered, notice is hereby given to the said John H. Thompson & Company, their assigns or legal representatives, that if they or any of them desire to contest the said interference they should immediately put themselves in communication with the Commissioner of Patents, in order that the notices of declaration heretofore sent by and returned to the Office may be forwarded to them.

This notice will be published in the OFFICIAL GAZETTE for six consecutive weeks. If no appearance shall be entered at the expiration of the period of publication, the interference will be proceeded with as in case of default.

F. I. ALLEN,
Commissioner.

APPLICATIONS UNDER EXAMINATION.

Condition at Close of Business February 6, 1906.

Room No.	Divisions and subjects of invention.	Oldest new application and oldest action by applicant awaiting office action. Amended	New.	No. of applications awaiting action.
	Under fifteen days.			
308	XV. Bread, Pastry, and Confections, Making, Coating, Laminated Sheets and Fabrics, Fuel, Glass, Hydraulic Lime and Cement, Paper-Making, Paving, and Plastics.	Jan. 27	Dec. 8	358
221	I. Tillage, etc., Fences, and Railway Draft Appliances.	Jan. 26	Dec. 26	191
378	XXXVIII. Artesian and Oil Wells, Bottles and Jars, Care of Live Stock, Fishing and Trapping, Stationery, Stone-Working.	Jan. 24	Dec. 14	337
148	XXXII. Carbonating Beverages, Dispensing Beverages, Dispensing-Cans, Metallic Shipping and Storing Vessels, Packaging Liquids, Paper Receptacles, Refrigeration, Wooden Receptacles.	Jan. 24	Sept. 27	596

Communications to the Patent Office.

RULE 9. A separate letter should in every case be written in relation to each distinct subject of inquiry or application. Assignments for record, final fees, and orders for copies or abstracts must be sent to the Office in separate letters.

PATENTS

GRANTED FEBRUARY 13, 1906.

812,176. RECISION-ENGINE. FREDERICK D. ALTHAUSER, New York, N. Y. Filed June 21, 1905. Serial No. 266,230.

Claim.—1. A recision-engine comprising a rotary piston, its shaft, a loose piston-ring, piston end plates overlapping the ends of the ring to form a piston-chamber, suitable inlet and outlet ports in the piston and rollers for supporting the ring eccentric to the piston and its shaft.

2. A recision-engine comprising a rotary piston having radially-sliding oppositely-arranged wings, a piston-shaft, a loose piston-ring eccentric to the shaft, piston end plates overlapping the ends of the ring to form two piston-chambers and rollers for supporting the ring with its inner wall in engagement with the periphery of the piston at one point and inlet and outlet ports in the piston for controlling the admission and exhaust of steam.

3. A recision-engine comprising a rotary piston, its shaft, a loose piston-ring, means for supporting the ring eccentric to the shaft, piston end plates overlapping the ends of the ring, radially-sliding piston-wings engaging the inner wall of the ring, inlet and outlet ports in the piston and valves for controlling the admission and exhaust of steam.

4. A recision-engine comprising a rotary piston, its shaft, a piston-ring loosely mounted eccentric to the piston with one point of its inner wall in engagement with one point of the periphery of the piston, piston end plates overlapping the ends of the ring, radially-sliding piston-wings engaging the inner walls of the ring, ports in the piston upon opposite sides of each of the wings, reversing-disks and valves arranged to coact with the piston for controlling the admission and exhaust of steam to and from one or the other side of each piston-wing.

5. A recision-engine comprising a rotary piston, its shaft, a loose piston-ring supported eccentric to the shaft with one point of the inner walls of the ring in engagement with one point on the periphery of the piston, piston end plates overlapping the ends of the piston-ring, radially-sliding piston-wings engaging the inner walls of the piston-ring, ports in the piston opening through its periphery upon opposite sides of each of the piston-wings, reversing-disks carried by the piston end plates and inlet and outlet valves arranged to operate the reversing-disks and means for controlling the movement of the inlet and outlet valves.

6. The combination with the rotary piston of a recision-engine and its shaft, of a reversing-disk located at the inlet end of the piston for controlling the movement of the piston, an inlet-valve for controlling the movement of the disk and means for moving the inlet-valve.

7. The combination with the rotary piston of a recision-engine and its shaft, of a reversing-disk located at the inlet end of the piston for controlling the movement of the piston, an inlet-valve for controlling the movement of the disk, means for moving the inlet-valve and an adjustable cut-off for the inlet-valve.

8. The combination with the rotary piston, of a recision-engine and its shaft, of a loose ring supported eccentric to the piston with its inner walls at one point in engagement with the periphery of the piston, two oppositely-disposed radially-sliding piston-wings, means for yieldingly holding the wings in engagement with the inner walls of the piston-ring and piston end plates overlapping the ends of the ring.

9. The combination with the rotary piston of a recision-engine, its shaft, radially-sliding piston-wings and two sets of ports leading from the ends of the piston to the opposite sides of each piston-wing, of a reversing-disk fitted to the end of the piston arranged to open the one or the other set of ports and a valve arranged to move the reversing-disk to the opposite limits of its movements for controlling the movement of the piston in the one or the other direction.

10. The combination with the rotary piston of a recision-engine and its shaft, of an outlet-valve mounted on the shaft and a reversing-disk interposed between the end of the piston and the face of the said valve.

11. The combination with the rotary piston of a recision-engine and its shaft, of a valve, a reversing-disk interposed between the end of the piston and the face of the valve, a cam, means for reciprocating the valve and means controlled by the movement of the valve for bringing the cam into and out of engagement with the disk for moving the disk to the limits of its movements in both directions.

12. A recision-engine comprising a hollow casing, a loose piston-ring therein, a rotary piston, its shaft, means for supporting the piston-ring eccentric to the shaft, radially-sliding piston-wings, piston end plates overlapping the ends of the ring, inlet and exhaust ports in the casing, ports in the piston, an inlet-valve having its inlet-ports opening into the interior of the casing exterior to the piston, an outlet-valve having its outlet-port opening to the exhaust-port in the casing and reversing-disks interposed between the valves and the ends of the piston for controlling the passage of steam from the interior of the casing through the inlet-valve and piston to the outlet-valve upon the proper sides of the piston-wings.

13. A recision-engine comprising a rotary piston, its shaft, a piston-ring, oppositely-arranged piston-wings, rods passing through the shaft and springs interposed between the ends of the rods and the wings for holding the wings in yielding engagement with the inner wall of the piston-ring.

812,177. TYPE-WRITING MACHINE. ENGLAND J. BARKER, Morgan Park, Ill. Filed Dec. 19, 1904. Serial No. 237,443.

Claim.—1. In a type-writing machine the combination of the carrier and manifold-ribbon spools carried thereby, stationary devices for intermittently moving said spools, a reel-frame supported independently of but movable with said carrier, and means carried by said reel-frame for supporting a roll of paper.

2. In a type-writing machine the combination of the carrier and manifold-ribbon spools carried thereby, stationary devices for intermittently moving said spools, a reel-frame supported independently of but movable with said carrier, and means carried by said reel-frame for supporting two independent rolls of paper.

3. In a type-writing machine the combination of the carrier, type mechanism, inking devices for making the original impression therefrom, manifold-ribbon spools carried by said carrier, stationary devices for intermittently moving said spools, a reel-frame sup-

ported independently of but movable with said carrier, and means carried by said reel-frame for supporting two rolls of paper.

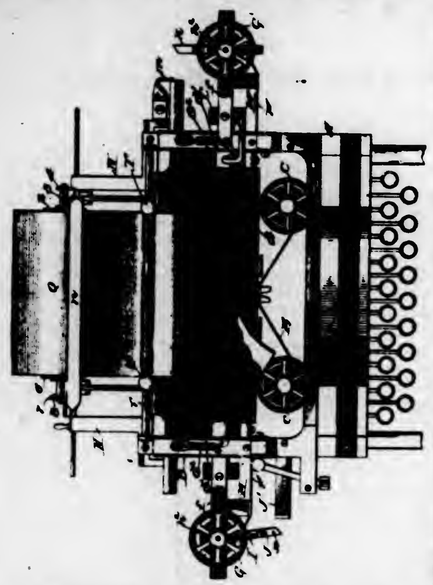
type mechanism, inking devices for making the original impression therefrom, manifold-ribbon spools carried by said carrier, stationary devices for intermittently moving said spools, a reel-frame sup-

steel comprising a fusible compound of sodium chlorid (NaCl), and potassium chlorid (KCl) substantially as described.

2. A melt or bath for hardening tools or articles of steel com-

Claim.—1. In combination in a machine for printing and banding postal cards and like articles, means for printing the cards in multiple and delivering them in direct lines in piles of the desired

ported independently of but movable with said carrier, and means carried by said reel-frame for supporting two rolls of paper.



4. In a type-writing machine the combination with the carrier and the ribbon-spools carried thereby, of a reel-frame supported independently of but movable with said carrier, means carried by said reel-frame for removably supporting a roll of paper, consisting of a stationary central boss and an oppositely-disposed pivoted boss normally pressing toward the same.

5. In a type-writing machine the combination with a reciprocal carrier, of a reel-frame supported independently of but movable with said carrier, means carried by said reel-frame for removably supporting a roll of paper, consisting of a stationary central boss and an oppositely-disposed pivoted boss normally pressing toward the same.

6. In a type-writing machine the combination with a reciprocal carrier, of a reel-frame supported independently of but movable with said carrier, means carried by said reel-frame for removably supporting a plurality of independent rolls of paper, said means consisting of a series of stationary central bosses mounted on one side of said frame and a corresponding number of oppositely-disposed pivoted bosses each normally pressing toward the stationary boss on the opposite side of said reel-frame.

7. In a type-writing machine the combination with the carrier, type mechanism, inking devices for making the original impression therefrom, and manifold carbon devices carried by said carrier, of a reel-frame supported independently of but movable with said carrier, means carried by said reel-frame for removably supporting a plurality of independent rolls of paper, said means consisting of a series of stationary central bosses mounted on one side of said frame and a corresponding number of oppositely-disposed pivoted bosses each normally pressing toward the stationary boss on the opposite side of said reel-frame.

8. In a type-writing machine the combination with the carrier and manifold-ribbon spools carried thereby, stationary devices for intermittently moving said spools, a reel-frame supported independently of but movably with said carrier, means carried by said reel-frame for supporting a roll of paper, and bearings in said means in which said roll of paper is removably journaled.

9. In a type-writing machine the combination with the carrier and manifold-ribbon spools carried thereby, stationary devices for intermittently moving said spools, a reel-frame supported independently of but movable with said carrier, means carried by said reel-frame for supporting two independent rolls of paper, and bearings in said means in which said rolls of paper are removably journaled.

10. In a type-writing machine the combination with the carrier, type mechanism, inking devices for making the original impression therefrom, manifold-ribbon spools carried by said carrier, stationary devices for intermittently moving said spools, a reel-frame supported independently of but movable with said carrier, means carried by said reel-frame for supporting two rolls of paper and bearings in said means in which said rolls of paper are removably journaled.

11. In a type-writing machine the combination with the carrier, and manifold-ribbon spools carried thereby, devices for intermittently moving said spools, a reel-frame supported independently of but movable with said carrier, means carried by said reel-frame for removably supporting a roll of paper, consisting of a stationary central boss, and an oppositely-disposed pivoted boss normally pressing toward the same.

12. In a type-writing machine the combination with the carrier and manifold-ribbon spools, carried thereby, devices for intermittently moving said spools, a reel-frame supported independently of but movable with said carrier means carried by said reel-frame for removably supporting a plurality of independent rolls of paper, said means consisting of a series of stationary central bosses mounted on one side of said frame, and a corresponding number of oppositely-disposed pivoted bosses each normally pressing toward a stationary boss on the opposite side of said reel-frame.

13. In a type-writing machine, the combination with a stationary supporting-frame, the reciprocal carrier thereon, and the ink-ribbon spools carried by said carrier, of a truck, reciprocal synchronously with said carrier, a reel-frame supported by said truck and comprising two uprights, a stationary bearing connected to one of said uprights and a movable bearing connected to the other upright, and means for centering a roll of paper comprising centering-bosses mounted on said bearings and arranged opposite each other, one of which is adapted to be moved toward and from the opposite boss.

14. In a type-writing machine, the combination with a stationary supporting-frame, the reciprocal carrier thereon, and the ink-ribbon spools carried by said carrier, of a truck, reciprocal synchronously with said carrier, a reel-frame supported by and connected to said truck and comprising two uprights, a stationary bearing connected to one of said uprights and a movable bearing connected to the other upright, and means for centering a roll of paper comprising centering-bosses mounted on said bearings and arranged opposite each other, one of which is adapted to be moved toward and from the opposite boss.

15. In a type-writing machine, the combination with a stationary supporting-frame, the reciprocal carrier thereon, and the ink-ribbon spools carried by said carrier, of a truck, two uprights secured to and arising from said truck which are connected to said carrier, and means for supporting a roll of paper consisting of a stationary bearing connected to one of said uprights, an arm pivoted to the other of said uprights and bearings connected to and carried by said arm.

16. In a type-writing machine the combination, with the carrier having brackets extending from the ends thereof, manifold-ribbon spools carried thereby, spindles on which said spools are mounted which are journaled in said brackets, and pawl-and-ratchet devices operatively connected to said spindles, of stationary means for actuating said pawl-and-ratchet devices, a reel-frame supported independently of but movable with said carrier, and means carried by said reel-frame for supporting a roll of paper.

17. In a type-writing machine the combination with a carrier having brackets extending from the ends thereof, manifold-ribbon spools carried thereby, spindles on which said spools are mounted which are journaled in said brackets, a ratchet-wheel secured to said spindle, and a lever fulcrumed thereon a pawl pivotally connected to said lever, of stationary means engaged by said levers, a reel-frame supported independently of but movable with said carrier, and means carried by said reel-frame for supporting a roll of paper.

18. The combination with the paper-feed carriage of a type-writing machine; brackets carried thereby having their ends projecting beyond the ends of said carriage; a ribbon-reel mounted on the unsecured ends of said brackets; a ratchet connected to each reel; and disengageable pawls projecting on opposite sides of said brackets and alternately cooperating with said ratchet-disks, whereby the ribbon may be automatically reeled from either of said reels, and called upon the other.

812,178. **MELT OR BATH FOR HARDENING STEEL.** SIMPLEY H. BRATSHAW, Hulme, Manchester, England, assignor to George Hunt, New York, N. Y. Filed Mar. 31, 1905. Serial No. 253,141.

Claim.—1. A melt or bath for hardening tools or articles of steel comprising a fusible compound of sodium chlorid (NaCl), and potassium chlorid (KCl) substantially as described.

2. A melt or bath for hardening tools or articles of steel comprising a compound of several salts soluble in water, any one of which separately melts at a higher temperature than the compound and a carburizing agent substantially as described.

812,179. **WHEEL.** CHARLES A. BRINLEY, Philadelphia, Pa., assignor to The American Pulley Company, Philadelphia, Pa., a Corporation of Pennsylvania. Filed Nov. 23, 1904. Serial No. 234,070.

Claim.—1. In a wheel, the combination with a sheet-metal rim comprising axially-alined members; of a primarily separate partition-flange extending beyond said rim and between said members, and, means extending through said partition-flange and rim, maintaining them in rigid relation, substantially as set forth.

2. In a wheel, the combination with a sheet-metal rim comprising axially-alined members having inwardly-turned flanges; of a primarily separate partition-flange extending beyond said rim and between said flanges, and, means extending through said partition-flange and rim, maintaining them in rigid relation, substantially as set forth.

3. In a wheel, the combination with a sheet-metal rim comprising axially-alined members forming opposed semicylindric sections; of a partition-flange formed of primarily separate semicircular sections extending beyond said rim and between said members, substantially as set forth.

4. In a wheel, the combination with a sheet-metal rim comprising axially-alined members forming opposed semicylindric sections; of a partition-flange formed of semicircular sections extending beyond said rim and between said members; the joints between said rim-sections and said partition-flange sections being in staggered relation; and, means securing said rim-sections and partition-flange sections in rigid relation, substantially as set forth.

5. In a wheel, the combination with a sheet-metal rim comprising axially-alined sectoral members; of a partition-flange comprising sectoral members extending beyond said rim and between its members; and, means securing said members in rigid relation, substantially as set forth.

6. In a wheel, the combination with a sheet-metal rim comprising axially-alined sectoral members; of a partition-flange comprising sectoral members extending beyond said rim and between its members; the joints between said rim members and said flange members being in staggered relation; and, means securing said members in rigid relation, substantially as set forth.

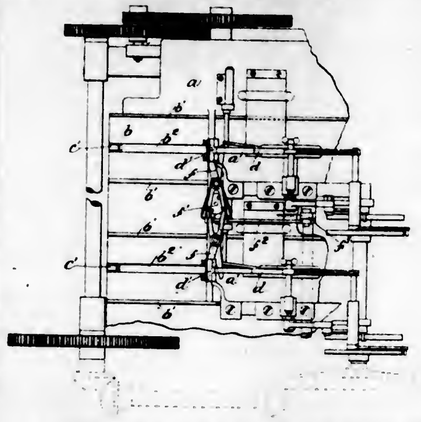
7. In a wheel, the combination with a sheet-metal rim comprising axially-alined sectoral members; of a partition-flange comprising sectoral members extending beyond said rim and between its members; the joints between said rim members and said flange members being in staggered relation; and, means securing said members in rigid relation, substantially as set forth.

8. In a wheel, the combination with a sheet-metal rim comprising axially-alined sectoral members having inwardly-turned flanges; of a partition-flange comprising sectoral members extending beyond said rim and between said flanges; the joints between said rim members and said flange members being in staggered relation; and, means securing said members in rigid relation, comprising spoke members and rivets extending through the same, substantially as set forth.

9. In a wheel, the combination with a sheet-metal rim comprising axially-alined sectoral members, having inwardly-turned flanges; of a partition-flange comprising sectoral members extending beyond said rim and between said flanges; spoke members upon opposite sides of said flanges; and, means extending through said spoke members and said flanges, securing the same in rigid relation, substantially as set forth.

812,180. **POSTAL-CARD PRINTING AND BANDING MACHINE.** WILLIAM H. BOWEN, Jersey City, N. J., assignor to Wentworth & Graham, New York, N. Y., a Firm. Filed Aug. 5, 1897. Serial No. 647,169.

Claim.—1. In combination in a machine for printing and banding postal cards and like articles, means for printing the cards in multiple and delivering them in direct lines in piles of the desired number to receptacles, the receptacles for receiving the cards, means for moving the piles from the receptacles in direct and parallel lines to banding devices and in position to be moved forward from the banding devices by contact of the next succeeding pile therewith in each parallel line, and means for banding the package.



2. In combination in a machine for printing and banding postal cards and like articles, means for printing the cards in multiple and in parallel lines and delivering them in piles of the desired number to receptacles, the receptacles, means for moving the piles from the receptacles in a direct line to banding devices, and also in like lines from the banders, and the banding devices.

3. In combination in an apparatus for printing and banding postal cards and like articles, means for printing the cards side by side and in parallelism and delivering them in direct lines in piles of the desired number to receptacles, the receptacles for receiving the cards, means for moving each of the parallel piles from the receptacles in a direct line to a banding device, means for banding the packages, said means for moving the piles from the receptacles in a direct line to the banding devices also effecting the discharge of the piles from the banders.

4. In combination in a machine for printing and banding postal cards and like articles, means for printing the cards side by side and delivering them in piles composed of the desired number to receptacles arranged side by side, the receptacles, means for moving the piles directly from the receptacles to banders appurtenant thereto, and the banding devices, the several packages being moved in the same horizontal plane.

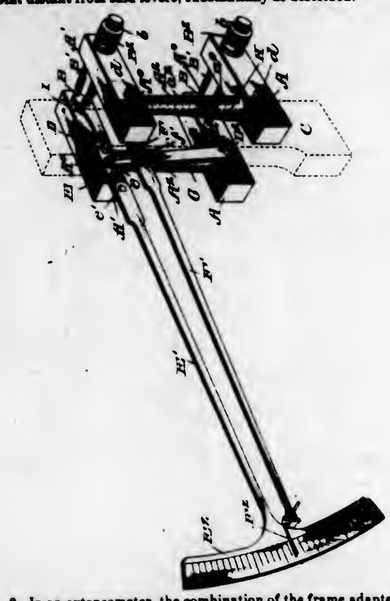
5. In combination in an apparatus for printing and banding postal cards and like articles, means for printing the cards side by side and delivering them in parallel piles composed of the desired number to receptacles for said piles, the receptacles, means for moving the cards in parallel lines and in the same horizontal plane and directly from said piles to banding devices appurtenant to each receptacle, and means for banding the packages, said means for moving the cards from the piles to the banding devices being adapted to eject the banded packages from the banders.

6. In combination in an apparatus for printing and banding postal cards and like articles, means for printing the cards in multiple side by side and for delivering them to receptacles, the receptacles arranged side by side, means for moving the piles in parallel lines from said receptacles to banding devices, a banding device arranged appurtenant to each receptacle for operating upon the pile of cards delivered therefrom, and means for moving the piles in parallel lines from the banders, each pile being moved to the banders and away therefrom by the contact of the next preceding pile.

812,181. **EXTENSOMETER.** WALTER CAPTELO, Sharon, Pa. Filed July 10, 1905. Serial No. 269,057.

Claim.—1. In an extensometer, the combination of the frame adapted to be connected to the specimen, levers pivoted to said frame, and links connected to said levers on respectively opposite

sides of their respective fulcra and also connected to the specimen at a point distant from said levers, substantially as described.



2. In an extensometer, the combination of the frame adapted to be connected to the specimen, levers pivoted to said frame, and links connected to said levers on respectively opposite sides of their respective fulcra and also connected to the specimen at a point distant from said levers, a graduated scale being carried by one of said levers and a pointer carried by the other lever, substantially as described.

3. In an extensometer, the combination of the frame adapted to be connected to the specimen, levers pivoted to said frame, and links connected to said levers on respectively opposite sides of their respective fulcra and also connected to the specimen at a point distant from said levers, with steadying-springs connected to said levers and to said frames for taking up the lost motion of said levers, substantially as described.

4. In an extensometer, the combination of the frame adapted to be connected to the specimen, levers pivoted to said frame, and links connected to said levers on respectively opposite sides of their respective fulcra and also connected to the specimen at a point distant from said levers, a graduated scale being carried by one of the levers and a pointer carried by the other lever, with steadying-springs connected to said levers and to said frame for taking up the lost motion of said levers, substantially as described.

5. In an extensometer, the combination of the frame adapted to be connected to the specimen, levers pivoted to said frame, and each provided with an arm or extension hinged thereto, and links connected to said levers on respectively opposite sides of their respective fulcra and also connected to the specimen at a point distant from said levers, substantially as described.

6. In an extensometer, the combination of the frame adapted to be connected to the specimen, levers pivoted to said frame, and each provided with an arm or extension hinged thereto, and links connected to said levers on respectively opposite sides of their respective fulcra and also connected to the specimen at a point distant from said levers, a graduated scale being carried by one of said arms and a pointer carried by the other arm, substantially as described.

7. In an extensometer, the combination of the frame adapted to be connected to the specimen, levers pivoted to said frame, and each provided with an arm or extension hinged thereto, and links connected to said levers on respectively opposite sides of their respective fulcra and also connected to the specimen at a point distant from said levers, with steadying-springs connected to said levers and to said frames for taking up the lost motion of said levers, substantially as described.

8. In an extensometer, the combination of the frame adapted to be connected to the specimen, levers pivoted to said frame, and each provided with an arm or extension hinged thereto, and links connected to said levers on respectively opposite sides of their respective fulcra and also connected to the specimen at a point distant from said levers, a graduated scale being carried by one of the arms and a pointer carried by the other arm, with steadying-springs connected to said levers and to said frame for taking up the lost motion of said levers, substantially as described.

9. In an extensometer, the combination of a laterally and longitudinally adjustable frame, holders mounted in said frame to engage the specimen, levers pivoted to said frame, links connected to said levers on respectively opposite sides of their respective fulcra, and holders carried by said links and connected to the frame and adapted to be connected to the specimen at a point distant from said levers, substantially as described.

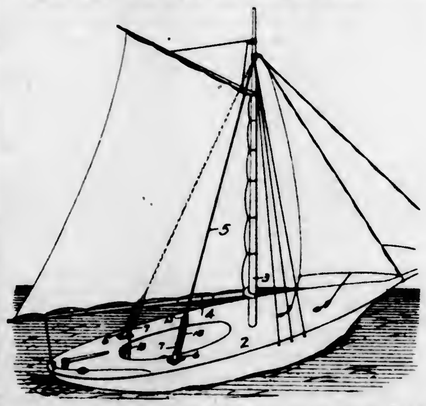
10. In an extensometer, the combination of a laterally and longitudinally adjustable frame, holders mounted in said frame to engage the specimen, levers pivoted to said frame, and links connected to said levers on respectively opposite sides of their respective fulcra, and holders carried by said links and connected to the frame and adapted to be connected to the specimen at a point distant from said levers, a graduated scale being carried by one of said levers and a pointer carried by the other lever, substantially as described.

11. In an extensometer, the combination of a laterally and longitudinally adjustable frame, holders mounted in said frame to engage the specimen, levers pivoted to said frame, and links connected to said levers on respectively opposite sides of their respective fulcra, and holder carried by said links and connected to the frame and adapted to be connected to the specimen at a point distant from said levers, with steadying-springs connected to said levers and to said frames for taking up the lost motion of said levers, substantially as described.

12. In an extensometer, the combination of a laterally and longitudinally adjustable frame, holders mounted in said frame to engage the specimen, levers pivoted to said frame, and links connected to said levers on respectively opposite sides of their respective fulcra, and holders carried by said links and connected to the frame and adapted to be connected to the specimen at a point distant from said levers, a graduated scale being carried by one of the levers and a pointer carried by the other lever, with steadying-springs connected to said levers and to said frame for taking up the lost motion of said levers, substantially as described.

13. In an extensometer, the combination with levers, of means for pivotally connecting said levers to the specimen, links connected to said levers respectively on opposite sides of their respective fulcra, and means for connecting said links to the specimen at a distance from the points of connection of said levers with the specimen, substantially as described.

812,182. **AUTOMATIC STAY-RELEASE.** LOUIS P. CHUTE, Minneapolis, Minn. Filed July 20, 1905. Serial No. 270,446.



Claim.—1. The combination, with a mast and stay, of means for automatically releasing said stay when pressure is applied laterally thereon, substantially as described.

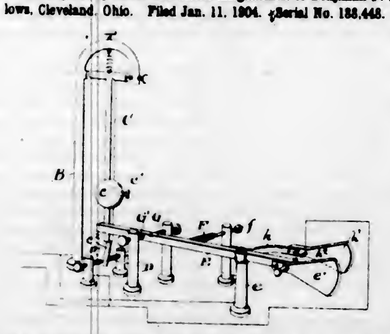
2. In a sail-boat, the combination, with the mast and boom, of a backstay, and means inserted into said stay and adapted to automatically release the same when the stay is struck by said boom, substantially as described.

3. The combination, with a sail-boat deck and mast and the boom, of a backstay, a housing, a frame pivoted therein, a toothed wheel mounted in said frame, a rope connected with said stay and normally held between said wheel and said housing and adapted to be released when said frame is oscillated, substantially as described.

4. The combination, with a sail-boat deck and mast, of a backstay, a housing, an oscillating frame mounted therein, a wheel carried by said frame and provided with a series of ratchet-teeth on each side and lower intermediate teeth, the wall of said housing being provided with teeth to engage with said ratchet-teeth and coöperating with the teeth between them, and a rope carried by said frame and connected with said stay and passing between the wall of said housing, and the intermediate teeth on said wheel and the pivot of said frame on said housing being out of line with the axis of said wheel and said stay, substantially as described.

5. The combination, with a mast and backstay, a housing, an oscillating frame mounted therein, a wheel carried by said frame, a rope connected with said stay and arranged to pass between said wheel and the wall of said housing and be gripped and held thereby, and the pivot of said frame being out of line with the axis of said stay, substantially as described.

812,183. **TELEGRAPH-KEY.** WILLIAM O. COFFE, Cleveland, Ohio, assignor, by direct and mesne assignments, to Benjamin F. Bellows, Cleveland, Ohio. Filed Jan. 11, 1904. Serial No. 188,448.



Claim.—1. In a telegraph-key, in combination, a gravity-vibrator adapted to swing by its own tendency and thereby make and break the circuit, a finger-key adapted to release the vibrator, and an adjacent finger-key adapted to open and close the circuit independently of the vibrator.

2. In a telegraph-transmitter, the combination of a stop and a spring coöperating therewith, each forming a terminal of an electric circuit, and a pendulum carrying one of said terminals, and means for holding said pendulum from swinging and allowing it to swing as desired.

3. In a telegraph-key, in combination, a stop, a spring coöperating therewith each forming a terminal of an electric circuit, and a pendulum carrying one of said terminals, and means for holding said pendulum from swinging and allowing it to swing as desired, a finger-piece for operating said means, and an adjacent finger-piece for closing the circuit independently of the pendulum.

4. The combination of an arm adapted to vibrate and make and break an electric contact, a key-lever engaging said arm to prevent its vibrating, a finger-piece on said key-lever for moving it to release said arm, and an adjacent finger-piece for making the contact independently of said arm.

5. The combination of a standard, a depending pendulum supported thereby, a spring carried by said pendulum and adapted to swing the same freely in both directions, an electric terminal coöperating therewith, and a key-lever adapted to control said pendulum.

6. The combination of a standard, a pendulum suspended therefrom, a spring carried by said pendulum at its lower end, a stop-screw forming an electric terminal which said spring is adapted to engage, and a key-lever adapted to bear against said pendulum and normally hold it with the spring out of contact with the stop-screw.

7. The combination of a standard, a pendulum suspended therefrom, a spring carried by said pendulum, a stop-screw forming an electric terminal which said spring is adapted to engage, a key-lever adapted to bear against said pendulum and normally hold it with the spring out of contact with the stop-screw, and a weight adjustably carried by said pendulum for varying its effective length.

8. The combination of a standard, a pendulum supported thereby and adapted to swing freely in both directions, an electric terminal coöperating therewith, and a key-lever adapted to control said pendulum, a finger-piece for operating said key-lever and an adjacent finger-piece for making dashes.

9. The combination of a pendulum, terminals coöperating therewith to make and break an electric circuit, a key-lever, and finger-pieces carried by said lever and adapted by one movement to swing the lever into engagement with said pendulum and by another movement to make and break an independent circuit.

10. The combination of a pendulum, terminals coöperating therewith to make and break an electric circuit and to transmit a rapid succession of short impulses through said circuit, and means for interrupting the movement of the pendulum, said means consisting of a key comprising a pivoted lever carrying a pair of finger-pieces, by one of which the key is given a movement to make and break another circuit.

11. In a telegraphic transmitter, in combination, a vibrator adapted to make and break an electrical circuit, a key-lever for controlling the operation of said vibrator, and an independent circuit-controller carried by said lever.

12. In a telegraphic-transmitter, the combination of a vibrating controller including a spring, said spring constituting one terminal of an electric circuit, a coöperating terminal, finger mechanism adapted to be operated by the thumb and finger pressing in opposite directions, lever mechanism operatable thereby and adapted to allow the controller to vibrate and bring said terminals into contact, and a pair of contacts additional to said controller, one of said contacts being operatively connected with the finger mechanism.

13. In a telegraphic transmitter, the combination of a contact and a spring coöperating therewith, each forming a terminal of an electric circuit, a vibrating circuit-controller having a uniform rate of oscillation and carrying one of said terminals, means for holding said controller from swinging and for allowing it to swing as desired, a pair of contacts additional to said controller, and finger means for operating such allowing means and for closing said last-mentioned contacts.

14. The combination with a controller adapted to vibrate and make and break an electric circuit, a lever adapted to engage said controller and prevent its vibrating, a finger-piece movable in one direction independently of said lever, a pair of contacts independent of said controller, one of said contacts being movable and rigidly connected with said finger-piece, whereby the movement of such finger-piece may close such contacts without moving said lever, and means for moving said lever in the opposite direction to release the controller.

15. The combination of a controller adapted to vibrate and make and break an electric circuit, a lever adapted to engage said controller and prevent its vibrating, a spring acting on said lever to normally hold it in such position, a finger-piece connected with the lever and adapted to move it away from the vibrator, a pair of contacts additional to the vibrator, and means connected with one of said contacts and movable with said lever in the direction to release the vibrator and movable independently of said lever in the opposite direction.

16. In a telegraphic transmitter, the combination of a contact and a spring coöperating therewith, each forming a terminal of an electric circuit, a vibrating circuit-controller having a uniform rate of oscillation and carrying one of said terminals, a member adapted to initiate the vibration of said controller, a spring acting on said member to hold the controller in idle position, a pair of contacts additional to said controller, and finger mechanism adapted to be operated by the thumb and finger pressing in opposite directions and serving by one of such movements to close said additional contacts and by the other to move said member to render the controller active.

17. In a telegraphic transmitter, the combination of a contact and a spring coöperating therewith, each forming a terminal of an electric circuit, a circuit-controller capable of making and breaking a circuit at a uniform rate and carrying one of said terminals, a lever normally engaging said controller to hold said spring and contact out of engagement, and means coöperating with said lever for making and breaking the circuit independently of said controller, substantially as set forth.

18. In a telegraphic transmitter, the combination of a controller adapted to vibrate and make and break a circuit, finger mechanism adapted to be operated by the thumb and finger pressing in opposite directions, a pair of contacts additional to said controller adapted to be closed by one of said pressures, and mechanism between the finger mechanism and the controller positively engaging the controller and actuatable by the opposite pressure to render said controller active.

19. In a telegraph instrument, the combination of a vibrator

19. In a telegraph instrument, the combination of a vibrator adapted to be held at one end and vibrate at the other and carrying a spring constituting one terminal of an electric circuit, a contact and a stop, a finger-piece and mechanism controlled thereby for normally holding said vibrator against the stop and with the contacts open but adapted to allow the vibrator to make a succession of contacts.

20. In a telegraphic transmitter, the combination of a vibrator, said vibrator carrying one terminal of an electric circuit and including a normally constrained spring, a coöperating terminal, a finger-piece, and lever mechanism operated thereby and adapted to hold the terminals out of contact with the spring constrained or to permit the vibrator to operate and bring said terminals into contact.

21. In a telegraphic transmitter, the combination of a controller capable of vibrating and making and breaking a circuit and including a spring, a restraining-arm therefor, a spring acting on said arm to cause it to prevent the controller from vibrating, a pair of contacts independent of said controller, and finger mechanism having two movements, by one of which it closes the independent contacts, and by the other of which it moves the arm against the action of the spring to render the controller active.

22. In a telegraphic transmitter, the combination of a vibrator capable of making and breaking a circuit at a uniform rate, key-lever mechanism normally engaging said vibrator and preventing it from operating, means coöperating with said mechanism for making and breaking the circuit independently of said vibrator, said mechanism being capable of a movement to withdraw it from engagement with said vibrator, substantially as set forth.

23. In a telegraphic instrument, the combination of a vibratory controller including a spring supported at one end, a contact and a stop on opposite sides of the path of vibration of said controller, a finger-piece, and mechanism controlled thereby for normally holding said controller against the stop with the contacts open, but adapted to render it active to vibrate and make a succession of contacts.

24. In a telegraphic transmitter, the combination of a circuit-controller, finger mechanism adapted to be operated by the thumb and finger pressing in opposite directions, a pair of contacts additional to the controller adapted to be closed by one of said pressures, and mechanism between the finger mechanism and the controller positively engaging the controller and actuatable by the other of said pressures to render said controller active.

25. In a telegraphic transmitter, the combination of a circuit-controller capable of making and breaking a circuit at a uniform rate, finger-key mechanism, a contact for said mechanism, mechanical means extending between said mechanism and said controller and normally preventing the operation of said controller, said mechanism being capable of two movements, by one of which it actuates said mechanical means to permit the operation of said controller, and by the other of which it engages its contact.

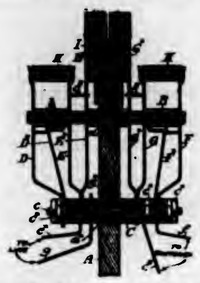
26. In a telegraphic transmitter, the combination of a circuit-controller, means for rendering said controller inactive, finger-key mechanism, a contact therefor, said mechanism being capable of two movements, by one of which it operates said means and renders the controller active, and by the other of which it is brought into operative relation with its contact.

27. In a telegraphic transmitter, the combination of a controller capable of making and breaking a circuit at a uniform rate, a pivoted arm normally preventing the operation of said controller, finger mechanism and a contact for said mechanism, said mechanism being capable of two movements, by one of which it moves the arm to permit the operation of the controller, and by the other of which it engages its contact.

28. In a telegraphic transmitter, the combination of a circuit-controller, a pivoted member, means acting on said member to hold said controller in inactive position, finger mechanism and a contact therefor, said mechanism being capable of two movements, by one of which it operates said member to render the controller active, and by the other of which it is brought into operative relation with its contact.

812,184. THERMAL PROTECTOR AND ALARM. FRANK B. COOK, Chicago, Ill. Filed Dec. 13, 1902. Serial No. 135,676.

Claim.—1. A protector, comprising a plate of metal, rods inserted transversely through said plate of metal, line and switchboard springs mounted upon said rods, the line-springs between the switchboard-springs and plate, heat-coil devices removably mounted upon the ends of said springs, a brass mounting-strip secured to the edge of said plate, the switchboard-springs normally pulling upon the heat-coil devices, and away from said plate, and a pair of parallel rows of carbon lightning-arresters mounted upon said brass strip, each carbon lightning-arrester being electrically connected with an adjacent line-spring together with a normally open alarm-circuit, each of said outer switchboard-springs being adapted, when released, to constitute part of the alarm-circuit.



2. A protector, comprising a flat plate of metal, rods of insulation inserted transversely through said plate, line and switchboard springs mounted on certain of said rods, the other rods of insulation serving to separate the different pairs of line and switchboard springs, and heat-coil devices mounted upon said springs, the switchboard-springs normally pulling upon the heat-coil devices, and away from said plate together with a normally open alarm-circuit, each of said outer switchboard-springs being adapted, when released, to constitute part of the alarm-circuit.

3. A protector, comprising a flat plate of metal, line and switchboard springs arranged in pairs and mounted in two rows, one at each side of said plate of metal, said springs all being insulated from said plate of metal, and heat-coil devices removably mounted upon the ends of said springs, the switchboard-springs normally pulling upon the heat-coil devices, and away from said plate together with a normally open alarm-circuit, each of said outer switchboard-springs being adapted, when released, to constitute part of the alarm-circuit.

4. In a self-contained piece of protective apparatus, the combination of a flat metal plate, line and switchboard springs mounted in pairs at one side of said plate, other line and switchboard springs mounted in similar pairs at the other side of said plate, all of said springs being insulated from said plate, heat-coil devices removably mounted upon the ends of said springs, the switchboard-springs normally pulling upon the heat-coil devices, and away from said plate, and a number of carbon lightning-arresters mounted along the edge of said plate, and arranged in two parallel rows extending between the two parallel rows of heat-coil devices, each carbon lightning-arrester being electrically connected with an adjacent line-spring, and also with the said flat metal plate together with a normally open alarm-circuit, each of said outer switchboard-springs being adapted, when released, to constitute part of the alarm-circuit.

5. The combination of a flat metal plate, a row of rods or strips of insulating material inserted transversely through the plate, another row of rods or strips of insulating material inserted through the plate, each of said last-mentioned rods being provided with a metal core, line-springs mounted on said last-mentioned rods and arranged at each side of the said plate, said line-springs being insulated from the said metal cores, switchboard-springs also mounted upon the said last-mentioned rods, the switchboard-springs at one side of the plate being electrically connected with the cores, the other switchboard-springs being insulated from the said cores, and heat-coil devices removably mounted upon the ends of said springs, the first-mentioned rods of insulation serving to maintain the proper distance between the pairs of line and switchboard springs.

6. The combination, in a self-contained piece of protective apparatus, of a flat metal plate, rods or strips of insulation inserted through the upper portion of said plate, said rods being connected at each side by metal rods, switchboard-springs suitably mounted and insulated from said plate, said switchboard-springs being normally out of contact with said metal rods, but adapted to make contact with said metal rods, line-springs, each line-spring being associated with a switchboard-spring, and heat-coil devices removably mounted upon said springs, the switchboard-springs normally pulling upon the heat-coil devices, and away from said plate together with a normally open alarm-circuit, each of said outer switchboard-springs being adapted, when released, to constitute part of the alarm-circuit.

7. The combination, in a protector, of a flat metal plate, suitable pieces of insulation inserted transversely through said plate, alarm-circuit contacts mounted on certain of said pieces of insulation, line and switchboard springs mounted on the other pieces of insulation, said switchboard-springs being adapted to engage the

said contacts, but adapted to be normally out of contact with the same, suitable heat-coil devices removably applied to the ends of said line and switchboard springs, the switchboard-springs normally pulling upon the heat-coil devices, and away from said plate, and carbon lightning-arresters arranged in two parallel rows along the edge of said metal plate, one block of each carbon lightning-arrester being electrically connected with an adjacent line-spring, and the other block of each lightning-arrester being electrically connected with said plate together with a normally open alarm-circuit, each of said outer switchboard-springs being adapted, when released, to constitute part of the alarm-circuit.

8. A self-contained piece of protective apparatus, comprising a flat strip adapted to serve as a mounting or support, line and switchboard springs mounted in pairs at each side of said strip, heat-coil devices removably applied to the ends of said springs, the switchboard-springs normally pulling upon the heat-coil devices, and away from said plate, and carbon lightning-arresters mounted in two parallel rows along the edge of said plate, one block of each lightning-arrester being electrically connected with an adjacent line-spring, and the other block of each lightning-arrester being electrically connected with a member which is adapted to be connected to ground together with a normally open alarm-circuit, each of said outer switchboard-springs being adapted, when released, to constitute part of the alarm-circuit.

9. In a device of the character described, the combination of a suitable support, outer switchboard-springs and inner line-springs suitably mounted at one side of said support, heat-coil devices removably applied to the ends of said springs, a normally open ground-circuit including said support, each line-spring when released being adapted to constitute part of said ground-circuit, and a normally open alarm-circuit, each of said outer switchboard-springs being adapted when released to constitute part of said alarm-circuit, and the line-springs being mounted intermediate of the said support and switchboard-springs.

10. In a device of the character described, the combination of a metal support, an inner line-spring and an outer switchboard-spring suitably mounted at one side of said support, a heat-coil device removably applied to the ends of said springs, a normally open ground-circuit including said support and line-spring in series, and an alarm-circuit normally open at two points and including said switchboard-spring, the line-spring being mounted intermediate of the support and switchboard-spring.

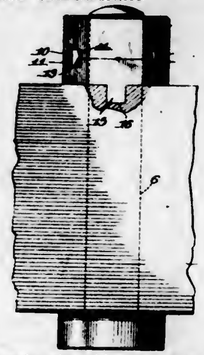
11. A thermal protector and alarm apparatus, comprising a metal support, a row of heat-coil devices mounted at each side of said support, a normally open ground-circuit including said support, line-terminals connected with the said heat-coil devices and all mounted at one side of said support, and switchboard-terminals also suitably connected with said heat-coil devices and all mounted at the other side of said support, said heat-coil devices having line and switchboard springs, the line-springs being mounted intermediate of the support and switchboard-springs, together with a normally open alarm-circuit, each switchboard-spring when released being adapted to constitute part of said alarm-circuit.

12. A thermal protector and alarm apparatus, comprising a metal support, line and switchboard springs mounted in pairs at each side of said support, heat-coil devices removably applied to each of said pairs of springs, line-terminals connected with said line-springs and all mounted at one side of said support, switchboard-terminals suitably connected with said switchboard-springs and all mounted at the other side of said support, a normally open ground-circuit including said support, each line-spring when released being adapted to constitute part of said ground-circuit, together with a normally open alarm-circuit, each switchboard-spring when released being adapted to constitute part of the alarm-circuit.

13. In a device of the character described, the combination of a suitable support, line and switchboard springs mounted on said support, an auxiliary spring between the said line and switchboard springs, a heat-coil device applied to the ends of the line and switchboard springs and holding the same normally under tension, a pair of metal rods both mounted between the line and switchboard springs, one rod being normally out of contact with the auxiliary spring and the other rod being normally out of contact with the switch-board-spring, whereby both rods are engaged by their respective springs when the switchboard-spring is released and moves away from the rods, together with a normally open alarm-circuit including said rods and including also said auxiliary and switchboard springs.

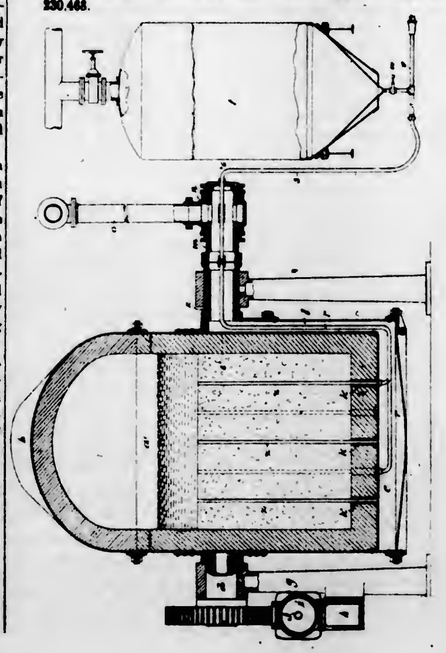
14. The improved thermal protector and alarm apparatus comprising a support with a row of thermal cut-outs at each side thereof, together with line-terminals and switchboard-terminals, the line-terminals all being arranged at one side of said support, and the switchboard-terminals all at the other side of said support, substantially as shown and described.

812,185. LOCK-NUT. HEBERIAN H. CRAWFORD, El Paso, Tex. Filed Dec. 19, 1904. Serial No. 237,586.



Claim.—The combination with a support having a plurality of rectangular openings formed therein, of a threaded bolt passing through said support, a nut engaging the threaded end of the bolt and having a pair of seating-recesses formed in its lower face and disposed parallel with the sides of the nut, said recesses being arranged at an acute angle to each other and of the same lengths as the adjacent sides of the nut, a washer having a smooth central bore and of the same shape as the nut interposed between the latter and the support and provided with oppositely-disposed depending angular lugs for engagement with the openings in the support, said washer being also provided with a plurality of seating-recesses arranged in triangular form and adapted to register with the seating-recesses of the nut when the latter is adjusted, and a locking-key adapted to engage said recesses and having its opposite ends bent laterally into engagement with the sides of the nut and washer, respectively.

812,186. APPARATUS FOR SMELTING AND CONVERTING ORES. ARTHUR M. DAY, Butte, Mont. Filed Oct. 29, 1904. Serial No. 230,468.



Claim.—1. In apparatus for smelting and converting ores, the combination of a smelting vessel having a wind-box and a number of twyers leading therefrom into the lower part of the smelting-chamber, and fusible twyer extensions leading upwardly from the twyers, substantially as described.

2. In apparatus for smelting and converting ores the combination of a smelting vessel provided with a wind-box having an air-blast connection and with a number of twyers leading from the wind-box into the smelting-chamber, fusible twyer extensions leading upwardly from the twyers, a separate compressed-air-supply connection with one of the twyers, and a closed receptacle for holding fluent material connected at the top with a source of compressed air and at the bottom with the air-supply connection leading to one of the twyers, substantially as described.

3. In apparatus for smelting and converting ores the combination of a smelting vessel provided with a wind-box having an air-blast connection and with a number of twyers leading from said wind-box into the smelting-chamber, fusible twyer extensions leading upwardly from the twyers, a separate compressed-air-supply connection with one of the twyers, and a closed receptacle for holding fluent material, having a valve-controlled connection with the air-supply connection leading to one of the twyers, substantially as described.

4. In apparatus for smelting and converting ores, a smelting vessel having an air-blast connection at the bottom and fusible twyer extensions leading upwardly into said vessel from the lower part thereof, substantially as described.

5. In apparatus for smelting and converting ores, the combination of a smelting vessel having an air-blast connection at the bottom and fusible twyer-tubes extending upwardly therefrom, substantially as described.

6. In apparatus for smelting and converting ores, the combination of a smelting vessel provided with twyers, a main air-supply connected with some of the twyers, and a closed receptacle for holding fluent material connected at the top with a compressed-air supply and at the bottom with an auxiliary pipe or passage leading from the air-supply to one of said twyers, substantially as described.

7. In apparatus for smelting and converting ores, the combination of a smelting vessel provided with twyers and mounted on trunnions, one of which is hollow and has a detachable tubular extension connected with the twyers and formed with a lateral opening, and an air blast or supply pipe provided with a sleeve in which the trunnion extension is adapted to turn and with which it forms an annular passage in communication with the lateral opening in said extension and with said air blast or supply pipe, substantially as described.

8. In apparatus for smelting and converting ores, the combination of a smelting vessel provided with twyers and mounted on trunnions one of which is hollow and has a detachable tubular extension connected with the twyers and formed with a lateral opening, an air blast or supply pipe and a branch pipe provided with a sleeve in which said trunnion extension is adapted to turn and with which it communicates through said lateral opening, said branch pipe having a swivel connection with the main blast-pipe whereby said trunnion extension when detached may be swung away from the associated trunnion, substantially as described.

9. In apparatus for smelting and converting ores, the combination of a smelting vessel provided with twyers and mounted on trunnions one of which has a detachable extension forming therewith an air-supply connection to the twyers, an air blast or supply pipe provided with a sleeve in which said trunnion extension is adapted to turn and through which it communicates with said pipe, an auxiliary air-blast pipe connected with a twyer and running through the main air-blast passage to said trunnion extension, and a flexible extension of said auxiliary pipe connected therewith by a joint which is adapted to be made and unmade by the coupling and uncoupling of the trunnion extension, substantially as described.

10. In apparatus for smelting and converting ores the combination of a smelting vessel provided with twyers, a main air blast or supply pipe connected with some of said twyers, a number of closed receptacles or reservoirs for holding fluent material, each connected at the top with a source of compressed air and having at the bottom a valve-controlled connection with an auxiliary blast-pipe leading from the source of compressed air to one of said twyers, substantially as described.

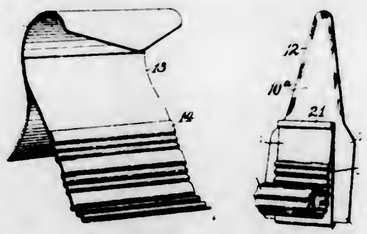
11. In apparatus for smelting and converting ores the combination of a smelting vessel provided with twyers, a main air-supply pipe connected with some of the twyers, a number of closed receptacles for holding fluent material connected at the top with a source of compressed air and each having at the bottom valve-controlled connections with a like number of auxiliary blast-pipes each leading to a twyer and connected with the source of compressed air, substantially as described.

12. In apparatus for smelting and converting ores the combination of a smelting vessel provided with twyers and mounted on trunnions, one of which has a detachable extension forming therewith an air-supply connection to the twyers, a compressed-air-supply pipe provided with an internally-recessed sleeve in which said trunnion extension is adapted to turn and through which it communicates with said pipe, a number of closed receptacles for holding fluent material connected at the top with a source of compressed air and having at the bottom valve-controlled connections with auxiliary blast-pipes which communicate with the compressed-air supply and have flexible connections with said trunnion extension, and pipes leading therefrom through the associated trunnion to certain twyers and adapted to make tight joints with the corresponding pipes in said extension when it is attached to said trunnion, substantially as described.

13. In apparatus for smelting and converting ores the combination of a smelting vessel provided with twyers and mounted on trunnions, one of which is hollow and is connected with some of the twyers and with an air-blast supply, and an auxiliary air-blast pipe leading through said hollow trunnion to one of the twyers, substantially as described.

14. In apparatus for smelting and converting ores the combination of a smelting vessel provided with twyers and mounted on trunnions, one of which is hollow and has a detachable tubular extension forming an air-supply connection for some of the twyers, a main air-blast pipe connected with said extension, an auxiliary passage leading from said hollow trunnion to one of the twyers and an auxiliary air-blast pipe leading into said extension and adapted to make a tight joint with the auxiliary passage in the trunnion when said extension is coupled thereto, substantially as described.

812,187. MAILING-TUBE SHEET AND WRAPPER. HARRY DEL MAR, New York, N. Y. Filed July 5, 1904. Serial No. 215,283.



Claim.—1. A device of the kind described, comprising a sheet adapted to be rolled up and to receive the address on the back, a second sheet secured to the first sheet, and an extension corrugated on both sides secured to the edge of the second sheet, whereby the three sheets can be rolled up together to form a tube the corrugated portions being constructed so that the corrugations shall nest one within the other.

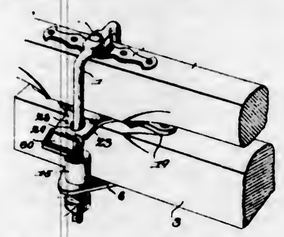
2. A device of the kind described, comprising a sheet adapted to be rolled up and to receive the address on the back, and an unbacked corrugated extension carried on the inner side of the sheet and adapted to roll up therewith, the corrugations being arranged on the extension so that they shall nest one within the other when the said extension is rolled.

3. A device of the kind described, comprising a sheet adapted to carry the address on its back, and an unbacked corrugated extension fastened to the sheet at a point between its end portions so that a part of the sheet shall overlap the extension and the corrugations on the extension being arranged so that when the sheet is rolled the corrugations shall nest one within the other.

812,188. WHIFFLETREE CONNECTION. OSCAR C. DICKERMAN, Gainesville, Tex. Filed July 26, 1905. Serial No. 271,209.

Claim.—1. A whiffletree-connector comprising a yoke to straddle a whiffletree and its support, a cross-bar connecting the ends of the yoke and movable longitudinally of the latter, and a spring exerting tension between the yoke and the cross-bar.

2. A whiffletree-connector comprising a yoke embracing the whiffletree, a plate provided with openings through which the ends of the yoke extend, and springs disposed to exert a tension between the plate and the yoke.



3. A whiffletree-connector comprising a yoke embracing the whiffletree, a plate provided with sleeves disposed upon opposite sides of the whiffletree and through which the ends of the yoke pass, and springs disposed within the sleeves and arranged to exert a tension between the plate and the yoke.

4. A whiffletree-connector comprising a yoke embracing the whiffletree, a plate engaging the ends of the yoke, a pivot-pin passing through the bow of the yoke through the whiffletree and through the plate, and a spring arranged to exert a tension upon the yoke.

5. A whiffletree-connector comprising a yoke embracing the whiffletree, a plate provided with sleeves disposed upon opposite sides of the whiffletree and through which the ends of the yoke are passed, springs disposed within the sleeves and arranged to exert a tension between the plate and the yoke, a pivot-pin passing through the bow of the yoke through the whiffletree and through the plate, and a spring arranged to exert a pressure upon the yoke.

6. In a whiffletree-connector, bearing-plates secured to the whiffletree and to the member to which the whiffletree is connected, an elastic washer carried by one plate, and means for holding the plates in elastic coöperative relation.

7. In a whiffletree-connector, a yoke embracing the whiffletree and the member to which the whiffletree is connected, a plate secured to the member and provided with openings through which the ends of the yoke pass, bearing-plates disposed between the whiffletree and the member, an elastic washer carried by one plate, a spring arranged to exert a pressure upon the whiffletree and the bearing-plates.

8. In a whiffletree-connector, a bearing-plate secured to the whiffletree, a bearing-plate secured to the member to which the whiffletree is pivoted and having a rearwardly-extending rigid loop, and means for holding the plates in elastic coöperative relation

9. In a whiffletree-connector, a bearing-plate secured to the whiffletree, a bearing-plate secured to the member to which the whiffletree is pivoted and having a rearwardly-extending rigid loop provided with an intermediate opening, a yoke embracing the whiffletree and the member to which the whiffletree is connected, and an arm passing through the opening of the bearing-plate and a spring arranged to exert an elastic pressure upon the whiffletree and the bearing-plate.

10. A whiffletree-coupling comprising a yoke to straddle the whiffletree and its support, a cross-bar for connection with the support and engaged by the sides of the yoke, and a pivot-pin rigidly carried by the plate and engaging the bow of the yoke.

11. A whiffletree-coupling comprising a yoke to straddle the whiffletree and its support, a cross-bar for connection with the support and provided with openings for the slidable reception of the arms of the yoke, tension devices between the arms of the yoke and the cross-bar, and a pivot-pin piercing the bow of the yoke and engaged with the cross-bar.

12. A whiffletree-coupling comprising a yoke to straddle the whiffletree and its support, a cross-bar for connection with the support and provided with openings for slidably receiving the arms of the yoke, springs embracing the arms of the yoke and engaging the cross-bar, adjustable nuts fitted to the ends of the yoke and engaging the springs to vary the tension thereof, and a pivot-pin piercing the bow of the yoke and engaging the cross-bar.

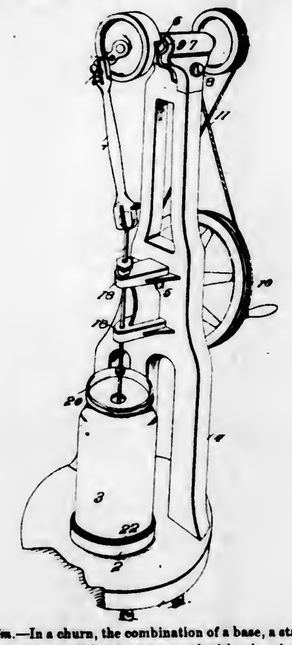
13. A whiffletree-coupling comprising a yoke to straddle the whiffletree and its support, a cross-bar for connection with the support and engaging the ends of the yoke, a pivot-pin rigidly carried by the plate and piercing the bow of the yoke, and a removable head carried by the top of the upper end of the pin and bearing against the top of the yoke.

14. A whiffletree-coupling comprising a yoke to straddle the whiffletree and its support, a cross-bar for connection with the support and having the ends of the yoke engaged therewith, a pivot-pin piercing the bow of the yoke and engaged with the cross-bar, and a wear-plate having an opening loosely receiving the pivot-pin and provided with a rearward extension having an opening receiving one of the arms of the yoke and terminating at its outer end in a brace-strap-receiving loop.

812,189. TOILET ARTICLE. HARRY A. DORR, Providence, R. I. Filed July 10, 1905. Serial No. 269,123.

Claim.—As an article of manufacture, a toilet article comprising a body formed of veneer embodying characteristics of an ordinary wooden toothpick, one end of said body being reduced to a point, the opposite end of said body being beveled to form a comparatively wide and thin extremity, said extremity being smoothly curved or rounded.

812,190. CHURN. JOHN W. DOWDEN, Pearl, La. Filed June 17, 1905. Serial No. 265,766.



Claim.—In a churn, the combination of a base, a standard rising therefrom and provided at its upper end with a bearing comprising two clamp members having a split metal ring between them which takes the wear and can be adjusted to fit the shaft, a shaft mounted in the bearing and having a crank-wheel at one end, a churn-body supported upon the base, a dasher having operative connection with the crank-wheel, and means for causing the crank-wheel to rotate.

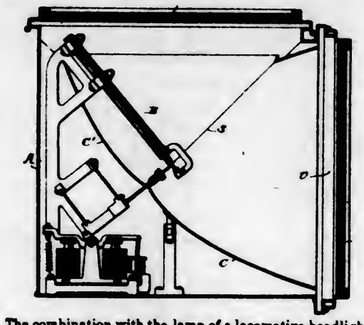
812,191. ADVERTISING DEVICE. ALFRED DUNHILL, South Hampstead, England. Filed Sept. 7, 1904. Serial No. 223,633.

Claim.—An advertising device consisting of a strip of paper bearing advertising matter rolled upon itself in the form of a tube and having its outer edge secured to the body and a string passed longitudinally through the roll, and a filling of material in imitation of tobacco within the roll, substantially as described.

812,192. LOCOMOTIVE-HEADLIGHT. EDGAR A. EDWARDS, Cincinnati, Ohio, assignor, by mesne assignments, to Metropolitan Trust & Savings Bank, trustee, a Corporation of Illinois. Filed Nov. 26, 1901. Serial No. 83,886.

Claim.—1. In a locomotive-headlight, the combination of a cas-

Claim.—1. In a locomotive-headlight, the combination of a casing open at both the front and top, and two intersecting paraboloidal reflectors having a common focus and arranged one to reflect the light from said focus forward and the other upward, substantially as set forth.



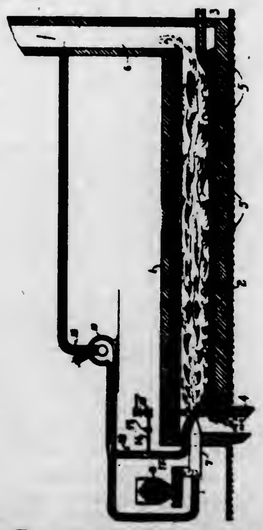
2. The combination with the lamp of a locomotive-headlight, of a paraboloidal reflector, the focus of which corresponds with the light of said lamp and arranged to project the light-rays forward, and a second paraboloidal reflector intersecting the first, having the same focus and arranged to project the light-rays upward, substantially as set forth.

3. The combination with the lamp of a locomotive-headlight, of a paraboloidal reflector, the focus of which corresponds with the light of said lamp and arranged to project the light-rays forward, a second paraboloidal reflector intersecting the first, having the same focus and arranged to project the light-rays upward, and a casing with end and top openings for the passage of the light-rays forward and upward and transparent coverings for said openings, substantially as set forth.

4. The combination in a locomotive-headlight, of a casing with openings at the top and front, and intersecting paraboloidal reflectors, having a common focus arranged to project light-rays forward and upward, and a lamp arranged to produce the flame at said focus, substantially as set forth.

812,193. PROCESS OF BLAST COMBUSTION.

BYRON E. ELDRED, Brooxville, N. Y., assignor to Combustion Utilities Company, New York, N. Y., a Corporation of New York. Filed Apr. 8, 1905. Serial No. 254,476.



Claim.—1. The process of producing a voluminous flame of large heating area which consists in projecting into an unobstructed hot-walled chamber of refractory material an ignited blast of suspended fuel carried by air containing sufficient products of combustion to retard burning and completing the combustion by radiant heat from the walls.

2. The process of producing a voluminous flame of large heating area which consists in projecting into an unobstructed chamber with roof of refractory heat-radiating material an ignited blast of suspended fuel carried by air containing sufficient products of combustion to retard burning and completing the combustion by radiant heat from the roof.

3. The process of producing a voluminous flame of large heating area which consists in projecting into an unobstructed hot-walled chamber of refractory material a blast of powdered coal carried by air containing sufficient products of combustion to retard burning and completing the combustion by radiant heat from the walls.

4. The process of producing a voluminous flame of large heating area which consists in projecting into an unobstructed chamber with roof of refractory heat-radiating material a blast of powdered coal carried by air containing sufficient products of combustion to retard burning and completing the combustion by radiant heat from the roof.

5. The process of burning pulverized fuel which consists in projecting pulverized fuel into a reverberatory furnace in susbension in a forcible current composed entirely of air and products of combustion, such products being in sufficient amount to retard combustion by the air of the current and completing combustion by radiant heat.

6. The process of producing differential heating which consists in forming a voluminous flame of large heating area in an unobstructed hot-walled chamber of refractory material by an ignited blast of suspended fuel carried by air containing sufficient products of combustion to retard burning and locally intensifying combustion at a desired point by a cross-jet containing air.

7. The process of producing differential heating which consists in forming a voluminous flame of large heating area in an unobstructed hot-walled chamber of refractory material by an ignited blast of suspended fuel carried by air containing sufficient products of combustion to retard burning and locally intensifying combustion at a desired point and to a desired degree by a cross-jet containing air and products of combustion in regulated proportions.

8. The herein-described process of intensifying the combustion of a blast-current of powdered coal diluted with products of combustion which consists in subjecting the same to the impingement of a high-pressure jet of air.

9. The process of intensifying the temperature of flame which consists in subjecting a fuel-laden current to impingement by an air-jet diluted with a neutral fixed gas.

10. The process of intensifying the temperature of flame which consists in subjecting a fuel-laden current to impingement by an air-jet diluted with gaseous products of combustion.

11. The process of intensifying the combustion of a blast-current of powdered fuel which consists in subjecting the same to impingement by a high-pressure jet of air diluted with products of combustion.

12. The process of regulating the temperature of flame which consists in subjecting a fuel-laden current to impingement by a jet of dilute air in such manner as to increase the normal temperature of combustion, and varying the proportion of diluent to air.

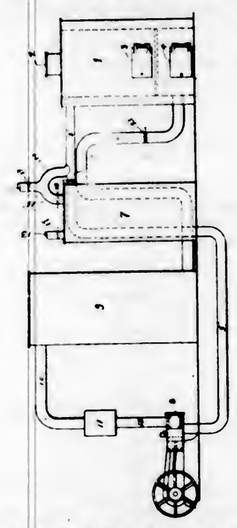
13. The process of obtaining regulated temperatures in a furnace which consists in producing a blast-flame of previously-unignited fuel, subjecting a current of the same composition to impingement by a dilute air-jet to locally intensify its combustion, and varying the proportion of diluent in the jet to vary the local temperature.

14. The process of obtaining regulated temperatures in a furnace which consists in producing a blast-flame of powdered coal diluted with products of combustion, acting on a similar current with an air-jet diluted with products of combustion to obtain a local high temperature, and varying that temperature by varying the proportion of diluent to air in the jet.

812,194. POWER-GAS PRODUCING AND CONSUMING APPARATUS.

CARLETON ELLIS, New York, N. Y., assignor to Combustion Utilities Company, New York, N. Y., a Corporation of New York. Filed May 11, 1905. Serial No. 260,986.

Claim.—1. In a power-gas producing and consuming apparatus, the combination of a gas-producer, a gas-engine, a cooled gas-delivery pipe connecting producer and engine; a cooled pipe connection abstracting products of combustion from the engine and delivering the same into the producer, and means opening directly into the atmosphere for admitting air into the cooled products of combustion.



2. In a power-gas producing and consuming apparatus, the combination of a gas-producer, a gas-engine, a cooling vessel adapted to contain water, a gas-delivery pipe connecting producer and engine and passing through said vessel, a pipe connection abstracting products of combustion from the engine and delivering the same into the producer, also passing through said vessel, means opening directly into the atmosphere for admitting air into the products of combustion cooled thereby and means also admitting vapors from said vessel into the products of combustion.

3. In a power-gas producing and consuming apparatus, the combination of a gas-producer, a gas-engine, a gas-delivery pipe connecting producer and engine, a cooling vessel adapted to contain water, a pipe connection abstracting products of combustion from the engine and delivering the same into the producer, and passing through said vessel, means opening into the atmosphere for admitting air into said products after passing the vessel, and means also admitting vapors from said vessel into said products of combustion.

4. In a power-gas producing and consuming apparatus, the combination of a gas-producer, a gas-engine, a gas-delivery pipe connecting producer and engine, means for returning products of combustion from the engine to the producer, means for cooling said products of combustion, and means for mingling the cooled products of combustion with cool air and with water-vapor.

5. In a power-gas producing and consuming apparatus, the combination of a gas-producer, a gas-engine, a gas-delivery pipe connecting producer and engine, a purifying device in said delivery-pipe, means for returning products of combustion from the engine to the producer, means for cooling said products of combustion, means for the admission of air to the cooled products and means for the admission of water-vapor.

6. In a power-gas producing and consuming apparatus, the combination of a gas-producer, a gas-engine, a water-cooled gas-delivery pipe connecting producer and engine, a water-cooled pipe connection abstracting products of combustion from the engine and delivering the same into the producer and means for introducing the water vaporized in said cooling into the products of combustion after cooling.

812,195. EXPLOSIVE COMPOUND.

RICHARD ESCALES, Munich-Schwabing, Germany. Filed Dec. 31, 1902. Serial No. 137,363.

Claim.—1. An explosive composition containing an oxygen-carrier and in addition an easily-oxidizable metal in the shape of metal wool for enhancing the dynamic effect of the said composition.

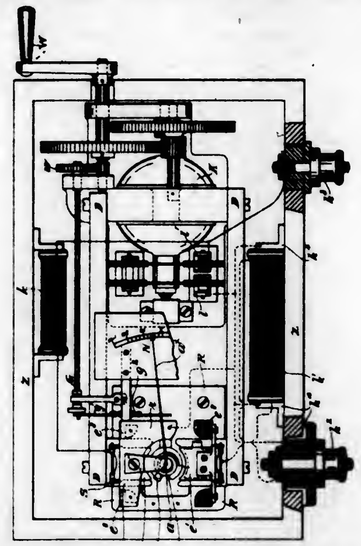
2. An explosive composition containing an oxygen-carrier and in addition aluminium wool for enhancing the dynamic effect of said composition.

3. An explosive composition consisting of Westfalite and aluminium wool, substantially as described.

4. An explosive composition containing ammonium nitrate and aluminium wool, substantially as described.

812,196. APPARATUS FOR MEASURING ELECTRIC RESISTANCES.

SYDNEY EVERSHED, Streatley, England, assignor to himself, and Evershed and Vignoles Limited, Chiswick, England, a Corporation. Filed Feb. 27, 1904. Serial No. 195,610.



Claim.—1. In combination, a generator of electric current, in close proximity to said generator, a direct-reading moving-coils ohmmeter with two coils, and a portable box inclosing the same for testing electrical resistance.

2. In combination, a generator of electric current; a direct-reading moving-coils ohmmeter in close proximity thereto; means for releasing the torsion of the conductors which convey current to and from the moving coils; and a portable box inclosing the same.

3. In combination, a generator of an electrical current, a direct-reading moving-coils ohmmeter in close proximity thereto; means for releasing the torsion of the conductors which convey current to and form the moving coils; electrically-guarded insulations to avoid leakage; and a portable box inclosing the same.

4. In combination, a hand-operated dynamo; a direct-reading moving-coils ohmmeter in close proximity thereto; duplex flexible conductors to the moving coils of said ohmmeter; fixed clamps adapted to alternately clamp and release the said conductors; means for actuating the clamps; and a portable box inclosing the same.

5. In combination, a direct-reading ohmmeter having moving coils and an index-finger rotatable relatively to fixed magnetic poles; flexible conductors to the moving coils of said ohmmeters; fixed clamps adapted to alternately clamp and release the said conductors; and means for actuating the said clamps.

6. In combination, a generator of electric current; a direct-reading moving-coils ohmmeter in close proximity thereto; guard-plates adapted to support the insulators of the apparatus; connections from the guard-plates to the source of current to prevent leakage; and a portable box inclosing said apparatus.

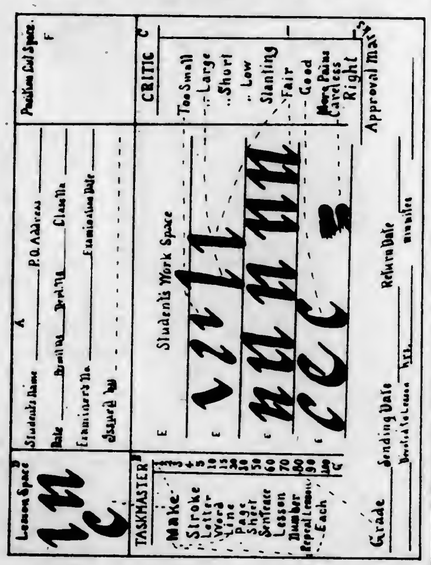
7. In combination, a generator of electric current; a direct-reading ohmmeter having moving coils and an index-finger rotatable relatively to fixed magnetic poles; said coils being connected at one end to the axis of said finger; a pair of flexible conductors connected to the other end of one of the movable coils; a pair of flexible conductors insulated from the said axis and connected to the other end of the other movable coil; six contacts about the said axis adapted to connect said flexible conductors to the line-circuits; and means for closing and releasing the said contacts with the said flexible conductors intermittently.

8. In combination, a hand-operated dynamo; a direct-reading ohmmeter having moving coils and an index-finger rotatable rela-

tively to a fixed magnet; said coils having their common terminal

tively to a fixed magnet; said coils having their common terminal connected with the axis of the said finger; a pair of flexible conductors connected to the said axis; a pair of flexible conductors upon an insulated sleeve of the said axis, and connected to the other end of one of the movable coils; a pair of flexible conductors upon an insulated sleeve of the said axis and connected to the other end of the other movable coil; six contact-clamps arranged about the said axis and adapted to make contact with said flexible conductors; circuits thereto from dynamo and external terminals; and means, operated from the dynamo, for causing the said clamp-contacts to intermittently and alternately make contact with, and release, the said flexible conductors.

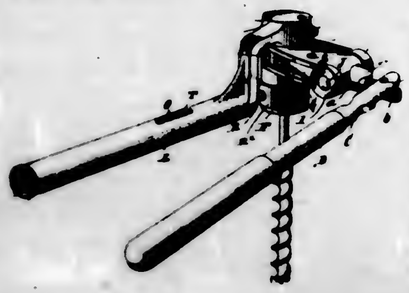
812,197. METHOD OF INSTRUCTION. HARVEY R. FULLER, Kirksville, Mo. Filed July 10, 1905. Serial No. 269,119.



Claim.—1. The herein-described method of instruction, constituting a substitute for oral written or sign methods comprising a critic a work-space adjacent to the said "critic" and adapted to be connected thereto by correction or approval lines as and for purposes fully set forth.

2. The herein-described system of instruction constituting a substitute for oral, written or sign methods of instruction comprising a lesson-space a "taskmaster" adjacent thereto and adapted to be joined to the said taskmaster by assignment-lines, and also comprising a work-space a "critic" adjacent thereto adapted to be joined to work in said work-space by correction or approval lines as and for purposes fully set forth.

812,198. BIT-BRACE. JACOB GREBERT, Buffalo, N. Y. Filed Aug. 27, 1904. Serial No. 222,426.



Claim.—1. A bit-brace comprising in combination, a pressure-bar and a stock mounted to rotate therein and be governed thereby, said stock having a ratchet-wheel rigid therewith, a handle having a head rotatable on said stock and carrying a pawl engaging said ratchet-wheel, and a braking device carried by said pressure-bar engaging said stock and resisting rotation on the return of the pawl.

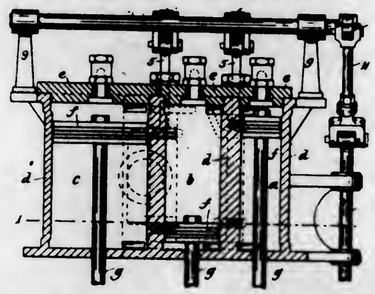
2. A bit-brace comprising in combination, a hollow pressure-bar having an offset arm, a stock mounted to rotate in said arm and having a ratchet-wheel rigid thereon, a handle rotatable on said stock and carrying a pawl engaging said ratchet-wheel, and a braking device comprising a brake-shoe and a rod mounted in said pressure-bar.

3. A bit-brace comprising in combination, a hollow pressure-bar having an offset arm, a stock mounted to rotate in said arm and having a ratchet-wheel rigid thereon, a handle rotatable on said stock and carrying a pawl engaging said ratchet-wheel, and a braking device comprising a brake-shoe, a rod carrying said brake-shoe mounted in the pressure-bar, a spring tending to force said rod inward to hold said brake-shoe against the stock, and means for drawing said rod outward against the action of said spring.

4. A bit-brace comprising in combination, a hollow pressure-bar having an offset arm and longitudinal slots at diametrically opposite points, a stock mounted to rotate in said offset arm and having a ratchet-wheel rigid thereon, a handle rotatable on said stock and carrying a pawl engaging said ratchet-wheel, and a braking device comprising a rod mounted in said pressure-bar and having its ends projecting therefrom and its outer end threaded, a brake-shoe at the inner end of said rod, an adjusting-nut fitting onto the threaded end of said rod, a pin passing through said rod and guided in the slots in the pressure-bar, a stop-bushing held in said pressure-bar, and spiral springs surrounding said bar and bearing with its ends against said pin and bushing, respectively.

5. A bit-brace comprising in combination, a pressure-bar and a stock mounted to rotate therein and be governed thereby, said stock having a ratchet-wheel rigid therewith, an operating-handle carrying a pawl engaging said ratchet-wheel and having a head rotatable on said stock provided with a radial shank, and a holding portion pivoted to said shank and capable of being swung at an angle to or in line with said shank, means for locking the handle and shank rigid when alined, and a braking device carried by said pressure-bar engaging said stock and resisting rotation on the return of the pawl.

812,199. COMPOUND STEAM-ENGINE. ROBERT P. GIBBONS, Kopu, New Zealand. Filed Feb. 4, 1903. Serial No. 141,983.

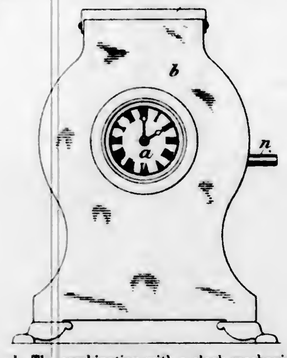


Claim.—1. A compound engine comprising a plurality of cylinders and pistons therein arranged adjacent to and parallel with each other, cranks for said pistons successively spaced in such manner that the crank for the larger piston precedes the crank for the next smaller piston by approximately one hundred and ninety degrees, an admission-valve and chamber for the high-pressure cylinder, an exhaust-valve and chamber for the low-pressure cylinder and a valve and chamber between each cylinder of the series but out of line therewith, each cylinder being connected by ports at each end with the valve-chambers preceding and following in series, and a common operating means for all the valves, said means actuating alternate valves in the series in opposite directions in timed relation to the operation of the pistons and in such manner that each valve will open the inlet-port to its piston before the piston completes its stroke.

2. A compound engine comprising a plurality of cylinders and pistons therein arranged adjacent to and parallel with each other, cranks for said pistons successively spaced in such manner that the crank for each piston precedes the crank of the next succeeding piston by approximately one hundred and ninety degrees, an admission-valve and valve-chamber for the initial cylinder of the series, an exhaust-valve and valve-chamber for the terminal cylinder, and a valve-chamber and valve arranged between each cylinder and the one succeeding in the series, each cylinder being connected by ports at its opposite ends with the cylinders preceding and following in the series, and a common operating means for all of the valves, said means constructed to actuate alternate valves in opposite directions in timed relation to the reciprocation of the pistons and in such manner that each valve will open the inlet-port to its cylinder before the piston therein completes its stroke.

3. In a compound engine the combination with the cylinders arranged alongside each other and connected at each end by ports leading to the cylinders immediately preceding and following in the series, the end cylinders of the series being provided respectively with admission and exhaust ports, pistons in said cylinders and connected with the shafts by cranks which are alternately substantially opposite each other, piston-valves seated in the cylinder-bodies and adapted to control said ports, a rock-shaft extending across the cylinder-heads and arms secured thereto and extending oppositely and each connected with one of the valves.

812,200. COIN-CONTROLLED CLOCK AND MONEY-BOX. HUGO GILLER, New York, N. Y. Filed Nov. 7, 1904. Serial No. 231,656.



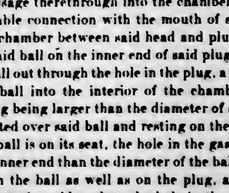
Claim.—1. The combination with a clock mechanism, of a lug on the winding-arbor, a stop-lever normally engaging said lug, means to move the stop-lever into abnormal position, a latch to hold said stop-lever in abnormal position, and a dog pivoted on the latch in the path of said lug and free to move in one direction only, substantially as described.

2. The combination with a clock mechanism, of a lug on the winding-arbor, a stop-lever pivoted adjacent to said arbor and normally engaging the lug thereon to prevent the winding of the clock, means to disengage said stop-lever, and a latch to hold said stop-lever in abnormal position and pivoted adjacent to the winding-arbor to be operated by the movement of the lug thereon to disengage said stop-lever, substantially as described.

3. The combination with a clock mechanism, of a lug on the winding-arbor, a stop-lever pivoted adjacent to said arbor to engage said lug, means to move the stop-lever into abnormal position, a latch to hold said stop-lever in abnormal position and pivoted adjacent to the arbor, and a dog pivoted on said latch in the path of said lug on the winding-arbor and free to move in one direction only, substantially as described.

812,201. METHOD OF MOUNTING AND AUTOMATICALLY ADJUSTING THE LAMPS OF MOTOR ROAD-VEHICLES. LÉONCE GIRARDOT, Puteaux, France. Filed Oct. 14, 1904. Serial No. 228,474.

Claim.—A device for automatically adjusting the lamps of motor-cars in accordance with changes in the direction of traveling comprising in combination a rotary lamp-support c pivotally mounted on a ball-bearing, a plate b supporting said ball-bearing and rigidly fixed to the cooling-jacket or the frame of the motor-car, a horizontal rod d attached by one end to the rotatory lamp-support c, a vertical rod d' connected by one end to the free end of the horizontal rod d, provided at its other end with a fork h, and pivoted in an intermediate point to the cooling-jcket or the frame of the motor-car, two collars g g mounted on the steering-rod f and adapted to engage with the forked end of the vertical rod d', and a spring i connecting one end of the lamp-support to a fixed part of the frame.



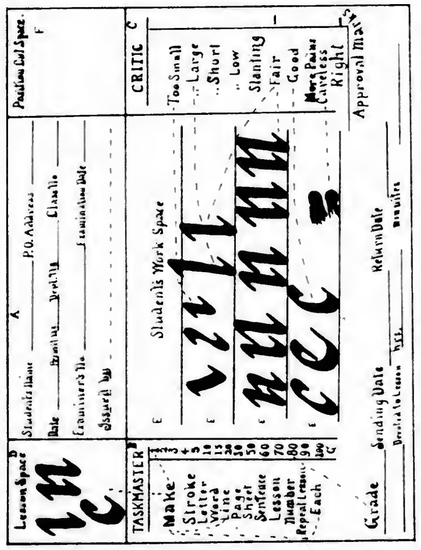
812,202. FLEXIBLE JOINT FOR PIPES. WARREN A. GREENLAW, Boston, Mass., assignor of one-half to Wesley W. Blair, Newton, Mass. Filed May 13, 1905. Serial No. 260,283.

Claim.—1. A flexible pipe-joint, comprising a chambered head having a neck with a passage therethrough into the chamber, a tubular plug having a separable connection with the mouth of said head, a ball inclosed in the chamber between said head and plug, a concave annular seat for said ball on the inner end of said plug, a stem projecting from said ball out through the hole in the plug, a passage through said stem and ball into the interior of the chamber, the passage through the plug being larger than the diameter of said stem, an annular gasket fitted over said ball and resting on the inner end of the plug when the ball is on its seat, the hole in the gasket being of less diameter at its inner end than the diameter of the ball so that the gasket is seated on the ball as well as on the plug, whereby the rearward movement of the ball carries with it the said gasket and washer, an annular flange on the interior of the head around the opening from the neck, said flange projecting into the chamber in the head, a coil-spring surrounding said flange, one end of said spring being seated on said metallic washer and the other end bearing against the rear wall of the chamber, said spring normally holding said ball and gasket to their seats in said tubular plug, and holding said ball and washer away from their seats on said flange.

2. A flexible pipe-joint, comprising a chambered head having a neck with a passage therethrough into the chamber, a tubular plug having a separable connection with the mouth of said head, a ball inclosed in the chamber between said head and plug, a concave annular seat for said ball on the inner end of said plug, a stem projecting from said ball out through the hole in the plug, a passage through said stem and ball into the interior of the chamber, the passage through the plug being larger than the diameter of said stem, an annular gasket fitted over said ball and resting on the inner end of the plug when the ball is on its seat, the hole in the gasket being of less diameter at its inner end than the diameter of the ball so that the gasket is seated on the ball as well as on the plug, an annular metal washer resting on the said gasket, the hole in the washer being of less diameter than that of the hole in the gasket and tapering so as to be seated on the ball as well as on the gasket, whereby the rearward movement of the ball carries with it the said gasket and washer, an annular flange on the interior of the head around the opening from the neck, said flange projecting into the chamber in the head, and having a concave seat for the ball when the ball is pushed backward from its seat on the plug, a coil-spring surrounding said flange, one end of said spring being seated on said metallic washer and the other

tively to a fixed magnet; said coils having their common terminal connected with the axis of the said finger; a pair of flexible conductors connected to the said axis; a pair of flexible conductors upon an insulated sleeve of the said axis, and connected to the other end of one of the movable coils; a pair of flexible conductors upon an insulated sleeve of the said axis and connected to the other end of the other movable coil; six contact-clamps arranged about the said axis and adapted to make contact with said flexible conductors; circuits thereto from dynamo and external terminals; and means, operated from the dynamo, for causing the said clamp-contacts to intermittently and alternately make contact with, and release, the said flexible conductors.

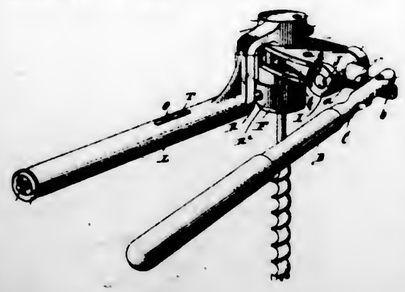
812,197. METHOD OF INSTRUCTION. HARVEY R. FULLER, Kirksville, Mo. Filed July 10, 1905. Serial No. 269,119.



Claim.—1. The herein-described method of instruction, constituting a substitute for oral written or sign methods comprising a critic a work-space adjacent to the said "critic" and adapted to be connected thereto by correction or approval lines as and for purposes fully set forth.

2. The herein-described system of instruction constituting a substitute for oral, written or sign methods of instruction comprising a lesson-space a "taskmaster" adjacent thereto and adapted to be joined to the said taskmaster by assignment-lines, and also comprising a work-space a "critic" adjacent thereto adapted to be joined to work in said work-space by correction or approval lines as and for purposes fully set forth.

812,198. BIT-BRACE. JACOB GEISERT, Buffalo, N. Y. Filed Aug. 27, 1904. Serial No. 223,436.



Claim.—1. A bit-brace comprising in combination, a pressure-bar and a stock mounted to rotate therein and be governed thereby, said stock having a ratchet-wheel rigid therewith, a handle having a head rotatable on said stock and carrying a pawl engaging said ratchet-wheel, and a braking device carried by said pressure-bar engaging said stock and resisting rotation on the return of the pawl.

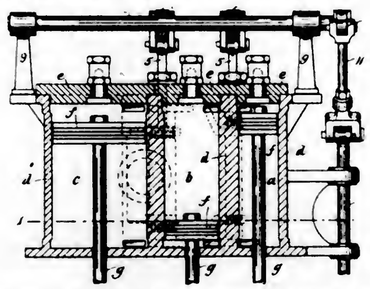
2. A bit-brace comprising in combination, a hollow pressure-bar having an offset arm, a stock mounted to rotate in said arm and having a ratchet-wheel rigid thereon, a handle rotatable on said stock and carrying a pawl engaging said ratchet-wheel, and a braking device comprising a brake-shoe and a rod mounted in said pressure-bar.

3. A bit-brace comprising in combination, a hollow pressure-bar having an offset arm, a stock mounted to rotate in said arm and having a ratchet-wheel rigid thereon, a handle rotatable on said stock and carrying a pawl engaging said ratchet-wheel, and a braking device comprising a brake-shoe, a rod carrying said brake-shoe mounted in the pressure-bar, a spring tending to force said rod inward to hold said brake-shoe against the stock, and means for drawing said rod outward against the action of said spring.

4. A bit-brace comprising in combination, a hollow pressure-bar having an offset arm and longitudinal slots at diametrically opposite points, a stock mounted to rotate in said offset arm and having a ratchet-wheel rigid thereon, a handle rotatable on said stock and carrying a pawl engaging said ratchet-wheel, and a braking device comprising a rod mounted in said pressure-bar and having its ends projecting therefrom and its outer end threaded, a brake-shoe at the inner end of said rod, an adjusting-nut fitting onto the threaded end of said rod, a pin passing through said rod and guided in the slots in the pressure-bar, a stop-bushing held in said pressure-bar, and spiral springs surrounding said bar and bearing with its ends against said pin and bushing, respectively.

5. A bit-brace comprising in combination, a pressure-bar and a stock mounted to rotate therein and be governed thereby, said stock having a ratchet-wheel rigid therewith, an operating-handle carrying a pawl engaging said ratchet-wheel and having a head rotatable on said stock provided with a radial shank, and a holding portion pivoted to said shank and capable of being swung at an angle to or in line with said shank, means for locking the handle and shank rigid when alined, and a braking device carried by said pressure-bar engaging said stock and resisting rotation on the return of the pawl.

812,199. COMPOUND STEAM-ENGINE. ROBERT P. GIBBONS, Kopa, New Zealand. Filed Feb. 4, 1903. Serial No. 141,923.

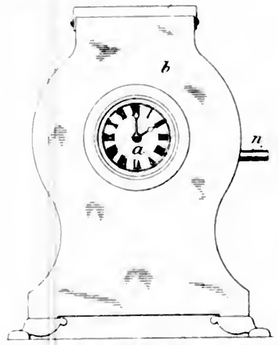


Claim.—1. A compound engine comprising a plurality of cylinders and pistons therein arranged adjacent to and parallel with each other, cranks for said pistons successively spaced in such manner that the crank for the larger piston precedes the crank for the next smaller piston by approximately one hundred and ninety degrees, an admission-valve and chamber for the high-pressure cylinder, an exhaust-valve and chamber for the low-pressure cylinder and a valve and chamber between each cylinder of the series but out of line therewith, each cylinder being connected by ports at each end with the valve-chambers preceding and following in series, and a common operating means for all the valves, said means actuating alternate valves in the series in opposite directions in timed relation to the operation of the pistons and in such manner that each valve will open the inlet-port to its piston before the piston completes its stroke.

2. A compound engine comprising a plurality of cylinders and pistons therein arranged adjacent to and parallel with each other, cranks for said pistons successively spaced in such manner that the crank for each piston precedes the crank of the next succeeding piston by approximately one hundred and ninety degrees, an admission-valve and valve-chamber for the initial cylinder of the series, an exhaust-valve and valve-chamber for the terminal cylinder, and a valve-chamber and valve arranged between each cylinder and the one succeeding in the series, each cylinder being connected by ports at its opposite ends with the cylinders preceding and following in the series, and a common operating means for all of the valves, said means constructed to actuate alternate valves in opposite directions in timed relation to the reciprocation of the pistons and in such manner that each valve will open the inlet-port to its cylinder before the piston therein completes its stroke.

3. In a compound engine the combination with the cylinders arranged alongside each other and connected at each end by ports leading to the cylinders immediately preceding and following in the series, the end cylinders of the series being provided respectively with admission and exhaust ports, pistons in said cylinders and connected with the shafts by cranks which are alternately substantially opposite each other, piston-valves seated in the cylinder-bodies and adapted to control said ports, a rock-shaft extending across the cylinder-heads and arms secured thereto and extending oppositely and each connected with one of the valves.

812,200. COIN-CONTROLLED CLOCK AND MONEY-BOX. HUGO GILLER, New York, N. Y. Filed Nov. 7, 1904. Serial No. 231,656.



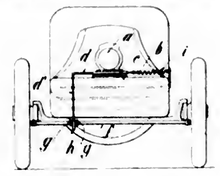
Claim.—1. The combination with a clock mechanism, of a lug on the winding-arbor, a stop-lever normally engaging said lug, means to move the stop-lever into abnormal position, a latch to hold said stop-lever in abnormal position, and a dog pivoted on the latch in the path of said lug and free to move in one direction only, substantially as described.

2. The combination with a clock mechanism, of a lug on the winding-arbor, a stop-lever pivoted adjacent to said arbor and normally engaging the lug thereon to prevent the winding of the clock, means to disengage said stop-lever, and a latch to hold said stop-lever in abnormal position and pivoted adjacent to the winding-arbor to be operated by the movement of the lug thereon to disengage said stop-lever, substantially as described.

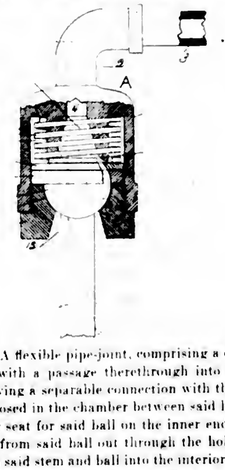
3. The combination with a clock mechanism, of a lug on the winding-arbor, a stop-lever pivoted adjacent to said arbor to engage said lug, means to move the stop-lever into abnormal position, a latch to hold said stop-lever in abnormal position and pivoted adjacent to the arbor, and a dog pivoted on said latch in the path of said lug on the winding-arbor and free to move in one direction only, substantially as described.

812,201. METHOD OF MOUNTING AND AUTOMATICALLY ADJUSTING THE LAMPS OF MOTOR ROAD-VEHICLES. LEONCE GIRARDOT, Puteaux, France. Filed Oct. 14, 1904. Serial No. 228,474.

Claim.—A device for automatically adjusting the lamps of motor-cars in accordance with changes in the direction of traveling comprising in combination a rotary lamp-support *c* pivotally mounted on a ball-bearing, a plate *b* supporting said ball-bearing and rigidly fixed to the cooling-jacket or the frame of the motor-car, a horizontal rod *d* attached by one end to the rotatory lamp-support *c*, a vertical rod *d'* connected by one end to the free end of the horizontal rod *d*, provided at its other end with a fork *h*, and pivoted in an intermediate point to the cooling-jeket or the frame of the motor-car, two collars *g g* mounted on the steering-rod *f* and adapted to engage with the forked end of the vertical rod *d'*, and a spring *i* connecting one end of the lamp-support to a fixed part of the frame.



812,202. FLEXIBLE JOINT FOR PIPES. WARREN A. GREENLAW, Boston, Mass., assignor of one-half to Wesley W. Blair, Newton, Mass. Filed May 13, 1905. Serial No. 260,283.

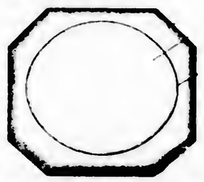


Claim.—1. A flexible pipe-joint, comprising a chambered head having a neck with a passage therethrough into the chamber, a tubular plug having a separable connection with the mouth of said head, a ball inclosed in the chamber between said head and plug, a concave annular seat for said ball on the inner end of said plug, a stem projecting from said ball out through the hole in the plug, a passage through said stem and ball into the interior of the chamber, the passage through the plug being larger than the diameter of said stem, an annular gasket fitted over said ball and resting on the inner end of the plug when the ball is on its seat, the hole in the gasket being of less diameter at its inner end than the diameter of the ball so that the gasket is seated on the ball as well as on the plug, whereby the rearward movement of the ball carries with it the said gasket and washer, an annular flange on the interior of the head around the opening from the neck, said flange projecting into the chamber in the head, a coil-spring surrounding said flange, one end of said spring being seated on said metallic washer and the other end bearing against the rear wall of the chamber, said spring normally holding said ball and gasket to their seats in said tubular plug, and holding said ball and washer away from their seats on said flange.

2. A flexible pipe-joint, comprising a chambered head having a neck with a passage therethrough into the chamber, a tubular plug having a separable connection with the mouth of said head, a ball inclosed in the chamber between said head and plug, a concave annular seat for said ball on the inner end of said plug, a stem projecting from said ball out through the hole in the plug, a passage through said stem and ball into the interior of the chamber, the passage through the plug being larger than the diameter of said stem, an annular gasket fitted over said ball and resting on the inner end of the plug when the ball is on its seat, the hole in the gasket being of less diameter at its inner end than the diameter of the ball so that the gasket is seated on the ball as well as on the plug, an annular metal washer resting on the said gasket, the hole in the washer being of less diameter than that of the hole in the gasket and tapering so as to be seated on the ball as well as on the gasket, whereby the rearward movement of the ball carries with it the said gasket and washer, an annular flange on the interior of the head around the opening from the neck, said flange projecting into the chamber in the head, and having a concave seat for the ball when the ball is pushed backward from its seat on the plug, a coil-spring surrounding said flange, one end of said spring being seated on said metallic washer and the other

end bearing against the rear wall of the chamber, said spring normally holding said ball and gasket to their seats in said tubular plug, and holding said ball and washer away from their seats on said flange.

812,203. JEWELRY-DISPLAY DEVICE. MAX HERZ, New York, N. Y. Filed June 5, 1905. Serial No. 263,752.



Claim.—1. A display device for jewelry, the same consisting of a suitable frame provided with an opening, a pad or cushion of soft material on which the jewelry may be mounted for display, the said pad being provided on its edge with a comparatively stiff member adapted to fit within the opening in the frame to retain the pad therein, a detached cover for said pad, the pad and cover being adapted to be inserted in and removed from said opening in the frame, the said cover fitting between said pad and opening, substantially as and for the purpose set forth.

2. A display device for jewelry, the same consisting of a frame provided with a suitable opening, a pad or cushion of soft material having a closed hand or hoop of suitably stiff and yielding material mounted on the edge of said pad and adapted to be sprung into the opening in said frame to retain the pad therein, a detached cover for said pad, the said pad with said cover adapted to be together inserted in and removed from said opening in the frame, the said cover fitting between said pad and opening, substantially as and for the purpose set forth.

812,204. PROCESS OF MANUFACTURING PHOTOGRAPHIC PAPERS. IGNAS HOFFSUMMER, Düren, Germany. Filed Sept. 16, 1905. Serial No. 278,775.

Claim.—1. A process for making photographic papers, consisting in a fibrous layer being laid over and attached to the raw paper and finally emulsioning said layer, substantially as described.

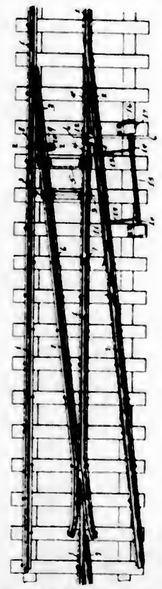
2. An improved photographic paper consisting of a layer of fibrous material laid over the raw paper and attached thereto by an adhesive substance, substantially as hereinbefore set forth.

812,205. RAILWAY-SWITCH. FRED A. HOWARTH, Johnstown, and JOHN J. MCKINLAY, Amsterdam, N. Y., assignors of one-fourth to said McKinlay, one-fourth to Frank D. Oliver, one-fourth to Louis K. Mayfender, and one-fourth to Ella Howarth, Johnstown, N. Y. Filed Sept. 7, 1905. Serial No. 277,333.

Claim.—1. In a railway-switch having main and side tracks with movable members whereby the switch can be opened, the combination with the movable track members; and spring mechanism for automatically closing the switch; of a switch-operating plate adjacent to the inner side of a stationary side-track rail and of a length greater than the distance between any two neighboring wheels of a car or train; a connection between said plate and a neighboring movable switch member; and means for operating said plate to open the switch.

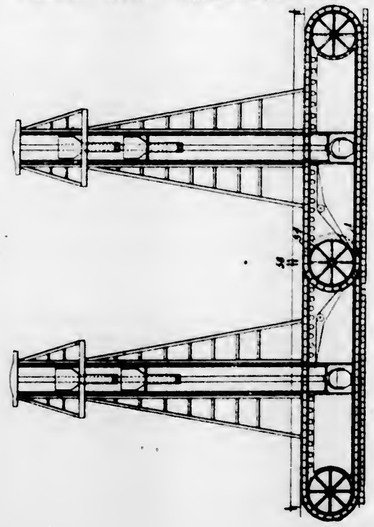
2. In a railway-switch having main and side tracks with movable members whereby the switch can be opened, the combination with the movable track members; and spring mechanism for automatically closing the switch; of a switch-operating plate adjacent to the inner side of a stationary side-track rail and of a length greater than the distance between any two neighboring wheels of a car or train; a connection between said plate and a neighboring movable switch member; an operating-handle connected with said plate; and an automatic spring-lock for said handle.

3. In a railway-switch having main and side tracks with movable members whereby the switch can be opened, the combination with the movable track members; and spring mechanism for automatically closing the switch; of a switch-operating plate adjacent to the inner side of a stationary side-track rail and of a length greater than the distance between any two neighboring wheels of a car or train; a connection between said plate and a neighboring movable switch member; a rock-shaft parallel with said plate and side track; a plurality of rocker-arms on said rock-shaft; connections between the respective rocker-arms and said plate; and means for rocking said rock-shaft.



4. In a railway-switch having main and side tracks with movable members whereby the switch can be opened, the combination with the movable track members; and spring mechanism for automatically closing the switch; of a switch-operating plate adjacent to the inner side of a stationary side-track rail and of a length greater than the distance between any two neighboring wheels of a car or train; a connection between said plate and a neighboring movable switch member; a rock-shaft parallel with said plate and side track; a plurality of rocker-arms on said rock-shaft; connections between the respective rocker-arms and said plate; a handle for rocking said shaft; and an automatic spring-lock for said handle.

812,206. FLOATING ELEVATOR OR LIGHTER. MICHAEL S. IVERSON, New York, N. Y. Filed Mar. 14, 1904. Serial No. 197,918.



Claim.—1. A band conveyer comprising a series of buckets, the band having upper and lower reaches, and the buckets being so attached that they are inverted while in the upper reach, a wheel over which said band runs upwardly, and a belt running upon said wheel and partly along the upper reach of said band, and covering the mouths of the buckets while running up over said wheel and after they leave the wheel.

2. A band conveyer comprising a sprocket-chain, a series of buckets attached thereto, the band having upper and lower reaches, and the buckets being so attached that they are inverted while in the upper reach, a sprocket-wheel for driving the band, a wheel over which said bands run upwardly, a belt running upon the last-mentioned wheel, an idle pulley for said belt between said wheels and immediately beneath the upper reach of said band, rolls supporting both the lower and upper reaches of said band and also the reach of said belt between said idle pulley and said upwardly-running band-wheel, and guards for coöperation with said rolls, said guards extending along said reaches in contiguity with the upper sides thereof.

3. A band conveyer comprising a sprocket-chain, a series of buckets attached at their open ends to said chain, the band having upper and lower reaches, wheels whereon the band runs, including a sprocket-wheel and an idle wheel over which the band runs upwardly, a bucket-closing belt running over said idle wheel and partly along the upper reach, rolls supporting both said belt and the upper and lower reaches of said band, a fixed guide for the lower reach of the band between said band-wheels, and a fixed guard overlying the upper reach of the band and curving around said band-wheels to the lower side thereof.

4. In combination, a band conveyer comprising a series of buckets and having a lower reach in which the buckets are supported in normal condition and an upper reach in which the buckets are inverted, means for driving the band, a bin having provision whereby it may discharge into the buckets of the lower reach, means for covering the mouths of the buckets while they travel from the lower to the upper reach and partly along the upper reach, and means for receiving the discharge from the buckets in the upper reach.

5. In combination, a band conveyer comprising a series of buckets and having a lower reach in which the buckets are supported in normal condition and an upper reach in which the buckets are inverted, wheels for operating the band, a bin having a floor interposed between the reaches and located closely adjacent to the lower reach, said floor being provided with a discharging-aperture above said lower reach, a belt traveling over one of the operating-wheels and covering the mouths of the loaded buckets while they travel to the upper reach, and means for receiving the discharge from the buckets in the upper reach.

6. In combination, a band conveyer comprising a series of buckets and having a lower reach in which the buckets are supported in normal condition and an upper reach in which the buckets are inverted, wheels for operating the band, a bin having a floor beneath which said lower reach travels, said bin being divided into a series of compartments, and said floor being provided with a series of gates overlying said lower reach, means for opening any gate independently of the others, a belt traveling over one of said wheels and covering the mouths of the loaded buckets while they travel upwardly and partly along the upper reach, and means for receiving the discharge from the buckets in the upper reach.

7. In combination, a band conveyer having upper and lower reaches, a bin having a sloping floor beneath the lower portion of which said lower reach travels and also having means for discharging into said lower reach, a hinged floor-leaf provided with a set of lifting-arms, a shaft extending along said leaf, chain connections from said shaft to said arms, whereby the winding of the chain on the shaft lifts the arms and leaf, a pinion upon said shaft, a gear meshing with said pinion, a sprocket-chain connected to said gear, and a hand-wheel having a sprocket-pinion over which said chain runs.

8. An elevator comprising a band conveyer provided with buckets and having a lower reach in which the buckets are supported in normal condition and an upper reach in which the buckets are inverted, means for discharging into the buckets in the lower reach, a belt for covering the mouths of the loaded buckets as they travel to and partly along the upper reach, a chute beneath said upper reach for receiving the discharge from the buckets, a bucket into which said chute discharges, and means for hoisting said bucket.

9. An elevator comprising a band conveyer provided with buckets and having a lower reach in which the buckets are supported in normal condition and an upper reach in which the buckets are inverted, a bin having means for discharging into the buckets in the lower reach, a belt for covering the mouths of the loaded buckets as they travel to and partly along the upper reach, a chute beneath the buckets in the upper reach at the end of said belt and provided with spouts upon its opposite sides, and gates for the spouts.

10. An elevator comprising a band conveyer provided with buckets and having a lower reach in which the buckets are supported in normal condition and an upper reach in which the buckets are inverted, wheels whereon the band runs, a bin having a floor above said lower reach and provided with means for discharging into said lower reach, a belt running over one of said wheels and covering the mouths of the loaded buckets, an idle pulley under said upper reach, whereon said belt runs, a chute beneath said upper reach at said idle pulley, and a spout or discharge for said chute at one side of said band conveyer.

11. An elevator comprising a band conveyer provided with buckets and having a lower reach in which the buckets are supported in normal condition and an upper reach in which the buckets are inverted, means for closing the filled buckets while they move to and along the upper reach, a bin discharging into the lower reach, a chute beneath said upper reach, spouts for said chute at the sides of said conveyer, gates for said spouts, shafts into which said spouts open, buckets into which said spouts discharge, and means for hoisting the last-mentioned buckets up said shafts.

12. The combination of a band conveyer provided with buckets and having a lower reach in which the buckets are supported in normal condition and an upper reach in which the buckets are inverted, a bin discharging into the lower reach, means for closing the filled buckets as they move to the upper reach, a chute beneath said upper reach, a spout for said chute at the side of said conveyer, a bucket into which said spout discharges, and means for weighing and hoisting the filled bucket.

13. An elevator comprising a band conveyer provided with buckets and having a lower reach in which the buckets are supported in normal condition and an upper reach in which the buckets are inverted, means for closing the buckets as they move upwardly and along the upper reach, a chute beneath the upper reach, spouts for said chute at the sides of said conveyer, shafts into which said spouts open, buckets into which said spouts discharge, means for hoisting said buckets up said shafts, a dumping-chute upon one side of the elevator for one of said shaft-buckets, and two dumping-chutes one above the other upon the other side of said elevator, one for each of said shaft-buckets.

14. An elevator comprising a plurality of band conveyers each provided with buckets and each having an upper reach and a lower reach, bins having means for discharging into the lower reaches, chutes beneath the upper reaches, and hoisting-buckets into which the chutes discharge.

15. An elevator comprising a plurality of band conveyers each provided with buckets and each having an upper reach in which the buckets are inverted and a lower reach in which the buckets are in normal condition, bins having floors sloping upwardly from both sides of the lower reaches and having means for discharging into the lower reaches, belts for closing the filled buckets as they move up and along the upper reaches, chutes beneath the upper reaches and each having discharges upon opposite sides, buckets for receiving the discharges from said chutes, means for hoisting said receiving-buckets, and dumping-chutes for said receiving-buckets.

16. An elevator comprising two adjoining band conveyers, each being provided with buckets and having a lower reach in which the buckets are in normal condition and an upper reach in which the buckets are inverted, a pair of wheels over which each band runs, a wheel in one pair being mounted side by side with a wheel in the other pair, belts closing the mouths of the buckets as they move up and along the upper reaches and chutes beneath said upper reaches.

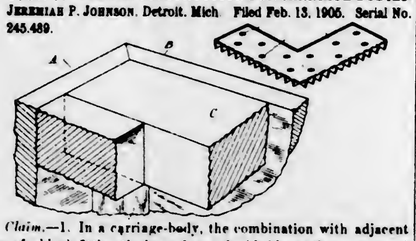
17. A lighter having bins whose flooring slopes downwardly from the sides toward the center of the vessel, partitions dividing said bins into compartments, gates in the flooring along the middle of the vessel, means for opening said gates independently of one another, two adjoining band conveyers, each conveyer being provided with buckets and having a lower reach in which the buckets are in normal condition and an upper reach in which the buckets are inverted, said lower reaches running beneath said gates, a pair of wheels over which each band runs, a wheel in one pair being mounted side by side with a wheel in the other pair, belts closing the mouths of the filled buckets as they move up and along the upper reaches, chutes beneath the upper reaches, shafts at the sides of each chute, buckets in the shafts into which the chutes discharge, means for hoisting the buckets, and dumping-chutes for the buckets.

18. A lighter having a deck and a bottom, a band conveyer provided with buckets and comprising a lower reach running along said

bottom and an upper reach running along the upper side of said deck, wheels over which the buckets run, flooring immediately overlying said lower reach and sloping upwardly therefrom to the sides of the lighter, partitions dividing the space between said deck and said flooring-apertures in the flooring above the buckets in said lower reach, gates for closing the apertures, a belt closing the mouths of the buckets as they pass from the lower to the upper reach, a chute at the termination of said belt and below said upper reach, a discharge for said chute, and means for hoisting the material discharged from the chute.

19. A lighter having bins arranged about a well, a conveyer to carry material from the bins to the well, and means for hoisting the material and discharging the same, comprising a superstructure or elevator above the well, a pair of buckets receiving material from the conveyer, means for hoisting the buckets, a chute for each bucket to receive the material therefrom, said chutes being arranged to discharge on opposite sides of the lighter, a third chute arranged above one of the others, discharging on the same side, and extending across the superstructure or elevator to receive material from the other bucket, as set forth.

812,207. **CORNER CONSTRUCTION FOR CARRIAGE-BODIES.** JEREMIAH P. JOHNSON, Detroit, Mich. Filed Feb. 13, 1905. Serial No. 245,489.



Claim.—1. In a carriage-body, the combination with adjacent sides, of a block fitting the inner faces of said sides at the corner, and a metallic angle bridging the joint between said block and sides around the corner, being provided with apertures for securing devices on opposite sides of said joint, and with its outer edges turned notched and embedded in the edges of the sides, and securing devices passing through said apertures into the sides and block.

2. In a carriage-body, the combination with adjacent sides, of a filling-block engaging the angle between the inner faces of said sides, of a metallic angle F having the turned outer flanges *c*, and the double series of apertures *a* and *b*, said angle being arranged to bridge the joint between the sides and block, and securing-pins passing through said double series of apertures and respectively engaging the block and the sides, and the flanges *c* being embedded in the edges of the sides, the pins in said sides being arranged near the inner faces thereof between said inner faces and said embedded flanges.

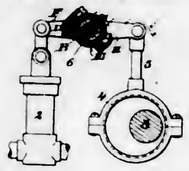
3. A metallic angle for box-corners, comprising an L-shaped plate having its outer edges turned to form flanges and notched to form a series of points and a double series of apertures for the securing nails or screws, substantially as and for the purpose set forth.

4. A carriage-body, comprising a sill, side and end panels adjoining each other, and secured respectively to the side and end of said sill, and a metallic angle bridging the joint between said sides and sill at the bottom thereof, being provided with notched flanges for embedding in the sides and end a series of apertures between said flanges and the line of joint with the sill, a second series of apertures in the portion underlapping the sill, and securing-pins engaging said apertures and embedded in the sides and sill.

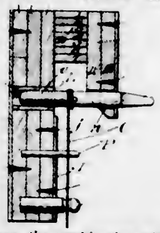
5. In a carriage-body, a sill formed of hard wood, thin side and end panels of soft wood adjoining each other, and secured respectively to the sides and end of said sill, an L-shaped metallic angle underlapping the joint between the panels and sill, being provided with projecting points at its outer edge for embedding in said panels, a series of apertures between said points and the line of joint with the sill, a second series of apertures in the portion underlapping the sill, securing-pins engaging the latter series for fastening the angle to said sill, and securing-pins engaging the first series and embedded in said panels, the latter being held from splitting by the embedded points of said angle and the securing of the same to the sill.

812,208. **CRANK.** WILLIAM R. HARLESSEMS, Two Rivers, Wis. Filed Sept. 9, 1905. Serial No. 277,776.

Claim.—A crank having a hollow hub, arms extending therefrom at either end, a longitudinal exterior groove in the hub, a split hub arranged over the groove, tightening-bolts connecting the split-hub members, whereby the latter may be adjusted longitudinally of said hub, and held in frictional contact against the latter, a supplementary screw in threaded connection with one member of said split hub, arranged to impinge against the bottom wall of said groove, whereby the hub is held against twisting under normal strain and also held against longitudinal movement, and an arm extending from the other member of the aforesaid split hub.



812,209. **HARP.** NICOLAUS KOLBY, Chicago, Ill., assignor to Henry Detmer, Chicago, Ill. Filed Nov. 20, 1905. Serial No. 288,229.



Claim.—1. In a harp, the combination with a principal neck having a bearing for a tuning-pin, of a supplemental neck also having a bearing for said tuning-pin, and a string winding upon said tuning-pin between said bearings.

2. In a harp, the combination of a principal neck for said harp, a supplemental neck, a bearing in said principal neck, a bearing in said supplemental neck, a tuning-pin supported in said bearings, and a string winding upon said pin between said principal neck and said supplemental neck.

3. In a harp, the combination of a principal neck with a bearing therein for a tuning-pin, a supplemental neck with a bearing therein for a tuning-pin, a tuning-pin supported in said bearings, said tuning-pin having a screw-thread upon one end thereof, and a string winding upon said tuning-pin.

4. In a harp, the combination of a principal neck, a supplementary neck, a bearing in said principal neck, a bearing in said supplemental neck, a tuning-pin supported in said bearing, said tuning-pin having means upon one end thereof adapted to engage suitable means in its bearing whereby the rotation of the pin moves said pin inwardly, and a string winding upon said pin.

5. In a harp, a neck comprising in combination a principal neck made up of a plurality of layers of material secured together, a supplemental neck made up of a plurality of layers of material secured together, and a web portion between said principal neck and said supplemental neck, said principal and supplemental necks being provided with bearings for a tuning-pin.

6. In a harp, a neck comprising in combination a principal neck made up of a plurality of layers of material secured together, a supplemental neck made up of a plurality of layers of material secured together, and a web portion connecting said principal neck and said supplemental neck, said web portion being also made up of a plurality of layers of material secured together.

7. In a harp, the combination of a principal neck, a supplemental neck, and a web portion between said principal and supplemental necks made up of a plurality of layers of material, said principal and supplemental necks having each a series of bearings for tuning-pins.

8. In a harp, the combination of a principal neck, a supplemental neck, and a web portion between said principal and supplemental necks, said web portion being made up of a plurality of layers of material, said principal and supplemental necks being reinforced with metallic strips.

9. In a harp, the combination of a principal neck, a supplemental neck, a web portion connecting said principal and supplemental necks, a metal strip reinforcing said principal neck and shaped to conform to the curves thereof and a metal strip reinforcing said supplemental neck, said strip also conforming to the curves of the neck.

10. In a harp, the combination of a principal neck, a supplemental neck of less width than the principal neck, a web portion connecting said principal and supplemental necks, a tuning-pin having one of its ends supported in the principal neck and its opposite end projecting through the supplemental neck, a metal plate secured to the principal neck and extending substantially the length of the latter, and a metal plate secured to the supplemental neck and extending substantially the length of said supplemental neck.

812,210. **PIPE-CUTTER.** ALEXANDER KOVACS, Chicago, Ill., assignor of one-half to Arpad M. Barothy, Chicago, Ill. Filed July 20, 1905. Serial No. 270,517.

Claim.—1. In a pipe-cutter, the combination of a casing, a bar slidably mounted in the casing, a movable pivot-stud rigidly secured to the slidable bar, a fixed pivot-stud rigidly secured to the casing, a wheel-bracket pivoted to the movable stud and provided with a slot embracing the fixed stud, a knife-adjusting plate extending at an angle to the bracket, a plate to which the knife-adjusting plate is pivoted, said latter plate being pivoted to the movable stud and provided with a slot embracing the fixed stud, an adjusting means carried by the plate and adapted to regulate the knife-carrying plate, a lower wheel on the bracket, an upper wheel, an arm to which the upper wheel is pivoted, a knife carried by the cutter-adjusting plate and means for moving the movable bar, substantially as described.

2. In a pipe-cutter, the combination of a fixed pivot, a relatively movable pivot, a bracket pivoted to the movable pivot and provided with a slotted portion embracing the pivot, a knife and knife-adjusting mechanism pivoted to the movable pivot and provided with a slot embracing the fixed pivot, and means for varying the distance between the two pivots, substantially as described.

3. In a pipe-cutter, the combination of a fixed pivot, a relatively movable pivot, a bracket pivoted to the movable pivot and provided with a slotted portion embracing the fixed pivot, a knife, a knife-adjusting plate, a plate to which the knife-adjusting plate is pivoted, said latter plate being pivoted to the movable pivot and provided with a slot embracing the fixed pivot, means for regulating the relative position of the pivoted plates and means for regulating the distance between the two pivots, substantially as described.

4. In a pipe-cutter, the combination of a fixed pivot, a relatively movable pivot, a bracket pivoted to the movable pivot and provided with a slotted portion embracing the fixed pivot, a knife, a knife-adjusting plate, a plate to which the knife-adjusting plate is pivoted, said latter plate being pivoted to the movable pivot and provided with a slot embracing the fixed pivot, means for regulating the relative position of the pivoted plates, a slidable bar to which the movable pivot is rigidly secured, a casing to which the fixed pivot is rigidly secured, and a handle carried by the casing and provided with a screw-threaded shank adapted to regulate the position of the slidable bar with respect to the casing, substantially as described.

5. In a pipe-cutter, the combination of a fixed pivot, a relatively movable pivot, a wheel-carrying bracket pivoted to the movable pivot and provided with a pair of slotted arms embracing the fixed pivot, knife-adjusting plates united in a solid head and positioned between the slotted bracket-arms, an inner plate between the knife-adjusting plates to which said plates are pivoted, said inner plate being pivoted to the movable pivot and provided with a slotted portion embracing the fixed pivot, a knife mounted between the knife-adjusting plates, an adjusting-screw carried by the inner plate and adapted to regulate the position of the knife-adjusting plates, a slidable bar to which the movable pivot is rigidly secured, a casing to which the fixed pivot is rigidly secured, and means for adjusting the movable bar, substantially as described.

6. In a pipe-cutter, the combination of a fixed pivot, a relatively movable pivot, a wheel-carrying bracket pivoted to the movable pivot and provided with a pair of slotted arms embracing the fixed pivot, knife-adjusting plates united in a solid head and positioned between the slotted bracket-arms, an inner plate between the knife-adjusting plates to which said plates are pivoted, said inner plate being pivoted to the movable pivot and provided with a slotted portion embracing the fixed pivot, a knife mounted between the knife-adjusting plates, an adjusting-screw carried by the inner plate and adapted to regulate the position of the knife-adjusting plates, a slidable bar to which the movable pivot is rigidly secured, means for adjusting the movable bar, and a wheel rotatably mounted on the knife-adjusting plates and provided with a circumferential rib in alinement with the cutting end of the knife, substantially as described.

7. In a pipe-cutter, the combination of a fixed pivot, a relatively movable pivot, a wheel-carrying bracket pivoted to the movable pivot and provided with a pair of slotted arms embracing the fixed pivot, knife-adjusting plates united in a solid head and positioned between the slotted bracket-arms, an inner plate between the knife-adjusting plates to which said plates are pivoted, said inner plate being pivoted to the movable pivot and provided with a slotted portion embracing the fixed pivot, a knife mounted between the knife-adjusting plates, an adjusting-screw carried by the inner plate and adapted to regulate the position of the knife-adjusting plates, a slidable bar to which the movable pivot is rigidly secured, a casing to which the fixed pivot is rigidly secured, means for adjusting the movable bar, a bracket pivoted to the knife-adjusting plates, a spring for holding the bracket forward under tension and a wheel carried by the bracket and provided with a circumferential rib in alinement with the cutting end of the knife, substantially as described.

8. In a pipe-cutter, the combination of a casing provided with a substantially bow-shaped arm, an upper wheel pivoted to the arm, an adjustable wheel-carrying bracket, a rear wheel secured thereto, a knife, an adjustable support for the knife, a bracket pivoted to the adjustable support, a spring bearing against the bracket, a wheel carried by the bracket and provided with a circumferential rib in alinement with the cutting end of the knife and means for regulating the position of the rear wheel and knife with respect to one another, substantially as described.

9. In a pipe-cutter, the combination of a knife, a rear wheel adjustably mounted with respect to the knife, a casing, an upwardly-extending supporting-arm secured to the casing, a pair of upper wheels, a cross-head provided with ears to which the wheels are pivoted, a pivot for securing the cross-head to the supporting-arm, a finger secured to the cross-head and extending through the supporting-arm and adjustable therein, and set-screws bearing against the finger for adjusting the position of the cross-head and the wheels pivoted thereto, substantially as described.

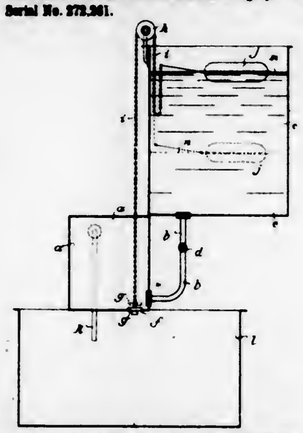
10. In a pipe-cutter, the combination of a casing, a bar slidably mounted in the casing, a bow-shaped supporting-arm upwardly extending from the casing and provided at its end with a suitable bearing-surface, a fixed pivot rigidly secured to the casing, a relatively movable pivot rigidly secured to the slidable bar, a screw-threaded handle-shank for regulating the position of the slidable bar, a bracket pivoted to the movable pivot and provided with a pair of slotted arms embracing the fixed pivot, a wheel pivoted to the opposite end of the bracket, knife-adjusting plates extending in angular relation to the bracket and united at their outer end, a knife rigidly secured to the knife-adjusting plates, an inner plate embraced by the knife-adjusting plates to which said plates are pivoted, said inner plates being pivoted to the movable pivot and provided with a slot embracing the fixed pivot, a neck outwardly extending from the inner plate and terminating in a head, and an adjusting-screw mounted in the head and adapted to regulate the position of the knife-adjusting plates, substantially as described.

11. In a pipe-cutter, the combination of a handle provided on its end with screw-threads, an upper relatively fixed roller, a rear roller adapted to be adjusted by the rotation of the screw-threaded handle, a cutter-carrying plate, an adjusting-screw adapted to regulate the cutter-carrying plate, and a resiliently-mounted guide-wheel provided with a rib in line with the end of the cutter, substantially as described.

12. In a pipe-cutter, the combination of a relatively fixed roller,

an adjustably-mounted rear roller, an adjustably-mounted wheel provided with a rib in line with the end of the cutter adapted to enter the groove formed by the cutter, substantially as described.

812,211. AUTOMATIC DISCHARGE FOR WASHING APPARATUS. CONSTANTIN KUHL, Vienna, Austria-Hungary. Filed Aug. 1, 1905. Serial No. 272,261.



Claim.—An automatic discharge device for washing apparatus comprising two receptacles *a* and *c*, a valve *f* at the bottom of the receptacle *a*, a plug *g* for said valve, a float *j* in the receptacle *c* and a connection from the said float to the plug *g* for controlling the valve by said float.

812,212. PAPER BOX OR CARTON. TOM J. LANDRUM, Louisville, Ky. Filed May 25, 1904. Serial No. 209,757.

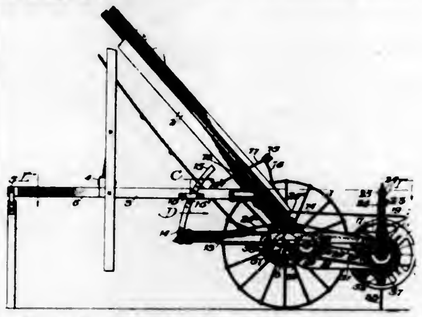
Claim.—1. A paper box or carton for the purpose set forth, comprising a paper box the bottom of which is composed of the inwardly-bent extensions of the four sides thereof, two of which are glued together and the other two loose and bent in and out or zigzag to receive the impact of the article dropped in the box, and the top or other end of said box closed by overlapped extensions of the back and front and a closing-strip formed by an extension of one side of the box, said closing-strip terminating in a tongue adapted to be inserted in the box at the front end thereof; together with a thick cardboard cover bent around three sides of the box with its edges projecting slightly beyond the latter, as herein shown and described.

2. In a paper box or carton for the purpose set forth, the combination, of a box made from a single blank comprising the body portion, the closing-flaps a^7, a^7 and a^8 at one end and the flaps a^4, a^5 and a^3 a^3 at the other end, the flaps a^4 and a^3 being overlapped and glued together to form the bottom of the box when the body of the blank is bent upon itself to form the body of the box, and the flaps a^6 a^6 bent inward upon said bottom and further bent in and out or zigzag above the same to form a yielding support, substantially as shown and described.

3. In a paper box or carton for the purpose set forth, the combination, of a box made from a single blank comprising the body portion, the closing-flaps a^7, a^7 and a^8 at one end and the flaps a^4, a^5, and a^3 a^3 at the other end, the flaps a^4 and a^3 being overlapped and glued together to form the bottom when the box is formed, while the flaps a^6 a^6 are bent inward upon said bottom and further bent in and out or zigzag above said bottom to provide a yielding support; together with a cardboard cover bent around three sides of the box and glued thereto, as herein shown and described.

812,213. HAY-LOADER. JOHN W. LATHAM, Chicago, Ill., assignor to International Harvester Company, a Corporation of New Jersey. Filed Oct. 11, 1905. Serial No. 282,866.

Claim.—1. In a hay-loader, the combination of an axle and carrying-wheels mounted thereon, an elevator and carrier frame mounted upon said axle and extending upward and forward therefrom, a supplemental frame pivotally mounted upon said axle and extending forward and in rear thereof, having its forward end adjustably connected with the elevator-frame, and a raking-cylinder mounted at the rear end thereof.



2. In a hay-loader, the combination of an axle and carrying-wheels mounted thereon, an elevator and carrier frame mounted upon said axle and extending upward and forward therefrom, a supplemental frame pivotally mounted upon said axle and extending forward and in rear thereof, having its forward end adjustably connected with the elevator-frame, and a raking-cylinder yieldingly mounted at the rear end thereof.

3. In a hay-loader, the combination of an axle and carrying-wheels mounted thereon, an elevator and carrier frame mounted upon said axle and extending upward and forward therefrom, a supplemental frame pivotally mounted upon said axle and extending forward and in rear thereof, having its forward end connected with the elevator-frame by means of bars secured to one of the frames and slidably connected with the other, and adjustable stops connected with the bars in a manner to limit the upward movement of the forward end of said supplemental frame, and a raking-cylinder mounted at the rear end thereof.

4. In a hay-loader, the combination of an axle and carrying-wheels mounted thereon, an elevator and carrier frame mounted upon said axle and extending upward and forward therefrom, a supplemental frame pivotally mounted upon said axle and extending forward and in rear thereof, having its forward end connected with the elevator-frame by means of bars curved concentrically relative to the axle and having one end secured to said supplemental frame and their opposite ends passing freely through loops secured to said elevator-frame, transverse openings in said bars, and pins received by said openings and contacting with said loops in a manner to limit the upward movement of the forward end of said supplemental frame, and a raking-cylinder yieldingly mounted at the rear end thereof.

5. In a hay-loader, the combination of an axle and carrying-wheels mounted thereon, an elevator and carrier frame mounted upon said axle and extending upward and forward therefrom, a supplemental frame pivotally mounted upon said axle and extending forward and in rear thereof and having its forward end connected with the elevator-frame, brackets secured to the rear end of said frame at opposite sides thereof, said brackets having vertically-arranged slots therein, a shaft extending across said frame and having its ends loosely mounted in said slotted brackets, and a raking-cylinder rotatably mounted upon said shaft.

6. In a hay-loader, the combination of an axle and carrying-wheels mounted thereon, an elevator and carrier frame mounted upon said axle and extending upward and forward therefrom, a supplemental frame pivotally mounted upon said axle and extending forward and in rear thereof and having its forward end connected with the elevator-frame, brackets secured to the rear end of said frame at opposite sides thereof, said brackets having vertically-arranged slots therein, a shaft extending across said frame and having its ends loosely mounted in said slotted brackets, springs operative to suspend the shaft in said brackets, and a raking-cylinder rotatably mounted on the shaft.

7. In a hay-loader, the combination of an axle and carrying-wheels mounted thereon, an elevator and carrier frame mounted upon said axle and extending upward and forward therefrom, a supplemental frame pivotally mounted upon said axle and extending forward and in rear thereof and having its forward end connected with the elevator-frame, brackets secured to the rear end of said frame and at opposite sides thereof, said brackets having vertically-arranged slots therein, a shaft extending across said frame and having its ends loosely mounted in said slotted brackets, links having their lower ends secured to said shaft and their upper ends passing loosely through openings in the upper ends of said brackets, and coiled springs surrounding the links above said brackets and operative to yieldingly support said shaft, and a raking-cylinder rotatably mounted upon said shaft.

8. In a hay-loader, the combination of an axle and carrying-wheels mounted thereon, an elevator and carrier frame mounted upon said axle and extending upward and forward therefrom, a supplemental frame pivotally mounted on said axle and extending forward and in rear thereof and having its forward end connected with the elevator-frame, brackets secured to the rear end of said frame and at opposite sides thereof, said brackets having vertically-arranged slots therein, a shaft extending across said frame and having its ends loosely mounted in said slotted brackets, links having their lower ends secured to said shaft and their upper ends passing loosely through openings in the upper ends of said brackets, coiled springs surrounding the links above said brackets, supplemental links having their upper ends secured to the upper ends of the first-mentioned links and their lower ends passing loosely through openings in the brackets, a cross-bar having its opposite ends secured to said supplemental links, and a raking-cylinder rotatably mounted upon said shaft.

9. In a hay-loader, the combination of an axle and carrying-wheels mounted thereon, an elevator and carrier frame mounted upon said axle and extending upward and forward therefrom, a supplemental frame pivotally mounted on said axle and extending forward and in rear thereof and having its forward end connected with the elevator-frame, a raking-cylinder mounted at the rear end of said supplemental frame, a cross-bar arranged above said cylinder and supported at opposite ends upon the frame, compressor-bars extending longitudinally above said elevator and carrier frame and having their lower ends slidably connected with said cross-bar.

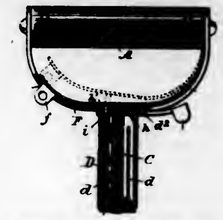
10. A raking mechanism for hay-loaders comprising, in combination, a fixed shaft, oppositely-disposed heads rotatably mounted upon said shaft, said heads being connected by means of bars secured to the peripheries thereof, a series of bands secured to said bars in a manner to have intervening spaces between the bands, a raking-cylinder mounted within said bands, and heads having rake-teeth and means for projecting and retracting said teeth through said spaces.

11. A raking mechanism for hay-loaders comprising, in combination, a fixed shaft, oppositely-disposed heads rotatably mounted upon said shaft, said heads being connected by means of bars secured to the peripheries thereof, a series of bands secured to said bars in a manner to have intervening spaces between the bands, said bands having inwardly-turned edges, a raking-cylinder mounted within said bands, and heads having rake-teeth and means for projecting and retracting said teeth through said spaces.

12. In a hay-loader, the combination of an axle and carrying-wheels mounted thereon, an elevator and carrier frame mounted upon said axle and extending upward and forward therefrom, a supplemental frame extending forward and in rear of said axle, comprising side bars and having its forward end adjustably connected with the elevator-frame, a raking-cylinder carried by the rear end of said supplemental frame, journal-boxes secured to said side bars and having said axle journaled therein, short shafts journaled in said boxes in rear of said axle and having pinions secured to their outer ends and sprocket-wheels to their inner ends upon opposite sides of said side bars, pinions secured to the axle and meshing with said first-named pinions, sprocket-wheels connected with said raking-cylinder, and sprocket-chains connecting the two sets of sprocket-wheels.

13. In a hay-loader, the combination of an axle and carrying-wheels mounted thereon, an elevator and carrier frame mounted upon said axle and extending upward and forward therefrom, a supplemental frame extending forward and in rear of said axle, comprising side bars and having its forward end connected with the elevator-frame, a raking-cylinder carried by the rear end of said supplemental frame, journal-boxes secured to said side bars and having said axle journaled therein, short shafts journaled in said boxes in rear of said axle and having pinions secured at their outer ends and sprocket-wheels to their inner ends upon opposite sides of said side bars, pinions secured to the axle and meshing with said first-named pinions, sprocket-wheels connected with said raking-cylinder, sprocket-chains connecting the two sets of sprocket-wheels, and shields depending from said side bars inside said sprocket-chains.

812,214. HANDLE ATTACHMENT FOR BOWLING-BALLS. SAMUEL H. LAW, HARRISON O. LAW, and SAMUEL H. LAW, Jr., New York, N. Y. Filed Apr. 18, 1905. Serial No. 256,230.



Claim.—1. A handle attachment for bowling-balls, comprising a handle portion and a laterally-expansible shank portion rotatably secured together, said shank being adapted to enter and frictionally engage the wall of a socket in a bowling-ball, and means whereby said shank may be expanded or contracted by independently rotating said handle or shank.

2. A handle attachment for bowling-balls, comprising a handle portion and a laterally-expansible shank rotatably secured thereto, said shank being adapted to enter a socket in a bowling-ball and frictionally engage the walls thereof, means operated by the rotation of the handle for expanding said shank, and a finger-piece projecting laterally from the upper end of said shank.

3. A handle attachment for bowling-balls, comprising a handle portion having a screw-threaded shaft or bolt projecting therefrom, a tubular shank rotatably mounted on said shaft, said shank being split at one end to permit of lateral expansion and contraction, and a conical nut on said shaft having its conical surface in contact with the split end of said shank, whereby independent rotation of said handle portion or shank will cause said shank to expand or contract.

4. A handle attachment for bowling-balls, comprising a handle portion and a laterally-expansible shank rotatably secured together, means whereby said shank will be expanded by independent rotation of said handle or shank, and means for locking said handle and shank against independent rotation.

5. In a handle attachment for bowling-balls, a handle-piece, a yoke secured to the ends thereof, a screw-threaded shaft fixedly secured to said yoke having a conical nut mounted thereon, a tubular shank mounted on said shaft between said yoke and said nut, said shank being split to permit of expansion by said nut, a spring-arm mounted on the handle portion of the attachment, a pin carried by said arm adapted to engage said yoke and said shank for preventing independent rotation thereof, and means for locking said strap and said yoke together.

812,215. CORN-HARVESTER. JOHN F. LEEPER, Alton, Ill. Filed May 29, 1905. Serial No. 262,784.

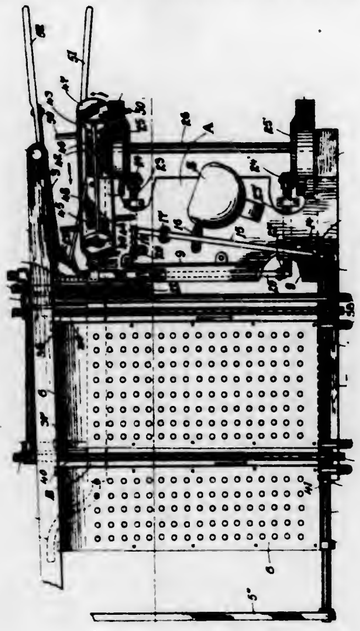
Claim.—1. In a harvester, a suitable platform, adapted to be advanced over the field, a depositing-surface for the cut material, a rock-shaft having a series of arms for retaining the material on the surface on which it has been deposited, a series of belts disposed in proximity to the depositing-surface, arms carried by the belts and projecting beyond the surface, suitable running-wheels for the machine, and intermediate gearing under the control of the operator for periodically setting the belts into motion and rocking the shaft to a releasing position for the arms carried thereby, substantially as set forth.

2. In a harvester, a suitable platform, a depositing-surface at the receiving side thereof inclining downward toward the discharging side, a longitudinally-disposed rock-shaft at the discharging side of the machine, a rotatable shaft parallel to the rock-shaft at the opposite side of the machine, a series of transverse belt conveyers disposed between the shafts, arms formed on the conveyers and projecting beyond the depositing-surface, running-wheels for the machine, an operating-lever under the control of the operator, and intermediate connections to simultaneously impart motion to the belt conveyers and rock the rock-shaft to a releasing position, the parts operating substantially as, and for the purpose set forth.

3. In a harvester, a suitable platform, a series of cutters, a permanently-advancing feed belt or chain for the stalks fed to the cutters, a transversely-disposed belt conveyer, means for setting the same intermittently into action for removing the contents from the side of the machine, substantially as set forth.

4. In a harvester, a depositing-surface for the cut material, a

platform, running-wheels therefor, bevel-gears on said wheels, pinions meshing with the gears, parallel shafts leading from the pinions, suitable cutters, intermediate connections between the latter and one of the shafts, a controlling-lever, a clutch member on one of the parallel shafts controlled by the depression of the controlling-lever, a belt conveyar for removing the contents deposited on the machine, intermediate connections between the conveyer and the clutch member for imparting motion to the conveyer upon depression of the controlling-lever, devices for temporarily retaining the material in position on the machine and means coupled to the controlling-lever for shifting the retaining devices and thereby releasing the contents upon the removal thereof by the conveyer, substantially as set forth.



812,216. POWER-CONTROLLING LEVER. GEORGE W. LORIMER, Piqua, Ohio. Filed June 14, 1902. Serial No. 111,625.

Claim.—1. The combination with a power-controlling lever and its actuating-handle, of a locking dog or bolt mounted thereon, and an actuating thimble or collar forming a section of the actuating-handle, and means concealed within the handle for operatively connecting the thimble with the bolt or dog.

2. The combination with a power-controlling lever, of a hollow actuating-handle secured thereto, a locking-plate, a locking-dog concealed in the handle, and a rotary thimble or collar mounted on said lever and connected with the dog for causing the same to engage and disengage the plate.

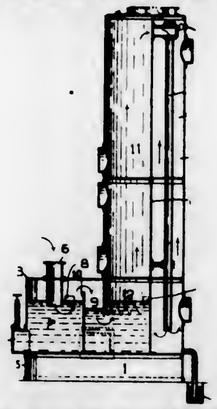
3. The combination with a power-controlling lever, of a locking-dog mounted thereon, a locking-plate engaged by and a rotary thimble or collar mounted on the lever and having a cam for holding the dog out of locking position or permitting it to hold the lever locked, at will.

4. The combination with a power-controlling lever, of a locking-bolt working in a longitudinal guide in said lever, an actuating thimble or collar mounted on the lever and connecting with the bolt, a rotatable locking-plate mounted on the lever, a pinion secured to said plate and a fixed rack as and for the purpose described.

5. The combination with a power-controlling lever, of a locking-bolt, a hollow handle concealing said bolt, an actuating-thimble forming a part of said handle, a locking-plate mounted on the lever, a fixed rack, an intermediate means between the rack and the locking-plate for rotating the same.

6. The combination with a power-controlling lever, of a locking bolt or dog carried thereby, an operating thimble or sleeve provided with a cam operatively connected with said bolt or dog and a locking-plate adapted to be engaged by said bolt or dog.

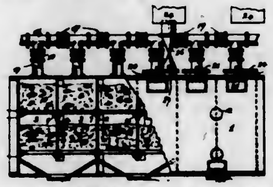
812,217. COMBINED GAS WASHER AND SCRUBBER. LEON P. LOWE, San Francisco, Cal. Filed May 17, 1904. Serial No. 208,346.



Claim.—1. In a device of the character described, the scrubber comprising a vertical shell, a vertical partition therein dividing the same into two chambers, a spray operating in the first chamber, a pipe conducting the gas from the top of said first chamber to the bottom of the second chamber, and a spray operating in the second chamber, substantially as described.

2. The combined gas washer and scrubber comprising a substantially L-shaped shell, the horizontal member being provided with an overflow, a gas-inlet extending below the level of the overflow, and a transverse partition dividing the horizontal member into two chambers, the shell of the vertical member on the side next the horizontal member being extended below the top of said horizontal member but not to the bottom thereof, a vertical partition in said vertical member dividing it into two chambers, a spray in the first chamber, a gas-pipe leading from the top of said first chamber to the bottom of the second chamber, and a spray in the second chamber, substantially as described.

812,218. GAS-PURIFIER. LEON P. LOWE, San Francisco, Cal. Filed Nov. 7, 1904. Serial No. 231,616.

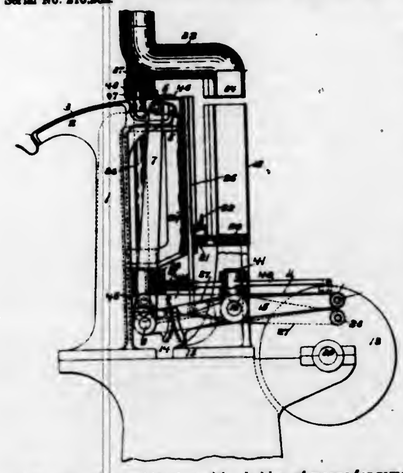


Claim.—1. A gas-purifier comprising a casing divided vertically into a horizontal series of chambers, and having connections at the top whereby the gas can be passed in succession through the chambers, each chamber having a vertical partition dividing it into two compartments connected at the bottom, and a door at the bottom of each chamber opposite to the vertical partition therein, substantially as described.

2. A gas-purifier comprising a casing divided vertically into a horizontal series of chambers, and having connections at the top whereby the gas can be passed in succession through the chambers, each chamber having a vertical partition dividing it into two compartments connected at the bottom, movable supports in each compartment for purifying material, and a door at the bottom of each chamber opposite to the vertical partition therein, substantially as described.

3. A gas-purifier comprising a casing divided vertically into a horizontal series of chambers, each chamber having a vertical partition dividing it into two compartments connected at the bottom, a pipe extending over, and parallel with said chambers, a valved connection from said pipe to each chamber, a valve in the pipe over each partition, movable supports in each compartment for purifying material, and an opening for removing the material from the bottom of each chamber, substantially as described.

812,219. FEEDING MECHANISM. WILLIAM S. LOCKETT, East Orange, N. J., assignor to International Cigar Machinery Company, New York, N. Y., a Corporation of New Jersey. Filed May 28, 1904. Serial No. 210,908.



Claim.—1. The combination with a holder, of means for removing a plurality of individual charges and conveying them separately to and assembling them at a common delivery-point, and a rolling mechanism, substantially as described.

2. The combination with a holder, of means for removing a plurality of individual charges of varying volume therefrom and conveying them separately to and assembling them at a common delivery-point, and a rolling mechanism, substantially as described.

3. The combination with a rolling mechanism, of a holder, means and for removing a plurality of individual charges from the holder transferring the charges separately to and assembling them in the rolling mechanism, substantially as described.

4. The combination with a holder having a plurality of compartments, of means for removing individual charges from the compartments and transferring them to and assembling them at a common delivery-poiat, and a rolling mechanism, substantially as described.

5. The combination with a rolling mechanism, of a holder, a charge-carrier adapted to carry a plurality of charges, means for moving the charge-carrier between the holder and the rolling mechanism, and means for causing the carrier to deliver the charges successively to the rolling mechanism, substantially as described.

6. The combination with a rolling mechanism, of a holder, a charge-carrier adapted to carry a plurality of charges of varying volume, means for moving the charge-carrier between the holder and the rolling mechanism, and means for causing the carrier to deliver the charges successively to the rolling mechanism, substantially as described.

7. The combination with a rolling mechanism, of a holder having a plurality of compartments, means for removing a charge from each compartment and for transferring the charges separately to and assembling them in the rolling mechanism, substantially as described.

8. The combination with a holder comprising a plurality of compartments, of means for removing individual charges from the holder and transporting them separately to and assembling them at a common delivery-point, substantially as described.

9. The combination with a holder, of a suction charge-separator operating to remove a plurality of individual charges from the holder and transport them to a common delivery-poiat, substantially as described.

10. The combination with a holder, of a suction charge-separator operating to remove a plurality of individual charges varying in volume from the holder and transport them to a common delivery-point, substantially as described.

11. The combination with a rolling mechanism, of a holder for granular material, a suction charge-separator operating to remove a plurality of charges from the holder, and means for actuating the separator to transfer the charges to the rolling mechanism, substantially as described.

12. The combination with a rolling mechanism, of a holder, a suction charge-separator operating to remove a plurality of charges varying in volume from the holder, and means for actuating the separator to transfer the charges to the rolling mechanism, substantially as described.

13. The combination with a holder for granular material, of suction charge-removing means, means for effecting relative movements between the holder and the removing means, whereby the removing means is positioned with respect to the material in the holder, and means whereby the material in the holder and the removing means are brought into juxtaposition.

14. The combination with a rolling mechanism, of a holder for granular material, suction charge-removing means, and means for moving the charge-removing means into taking position with respect to the holder and delivery position with respect to the rolling mechanism, and means whereby the material in the holder and the removing means are brought into juxtaposition.

15. The combination with a rolling mechanism, of a holder for granular material, a suction charge-removing device, and means for causing said device to remove charges from the holder and transfer them to the rolling mechanism, substantially as described.

16. The combination with a holder comprising a plurality of compartments, of charge-removing means coöperating with each compartment, and means for actuating said charge-removing means to remove charges from the compartments and to assemble them at a common delivery-point, said charge-removing means being constructed to remove charges of varying volume from different compartments, substantially as described.

17. The combination with a rolling mechanism, of a holder comprising a plurality of compartments, suction charge-removing means coöperating with each compartment, and mechanism for actuating said charge-removing means to remove charges from the compartments and deliver them to the rolling mechanism, substantially as described.

18. The combination with a rolling mechanism, of a holder comprising a plurality of compartments, suction charge-removing means coöperating with each compartment, said charge-removing means being constructed to remove charges of different volumes from different compartments, and means for actuating said charge-removing means to deliver the charges to the rolling mechanism, substantially as described.

19. The combination with a holder, of a suction charge-carrier having a plurality of operating-faces varying in area, means for producing a relative movement between the charge-carrier and the holder and for causing the faces to deliver at a common point, substantially as described.

20. The combination with a holder having a plurality of compartments, of a suction charge-carrier having a plurality of operating-surfaces, one for each compartment, said surfaces differing in area, and means for moving the carrier to bring its surfaces to a common discharging-point, substantially as described.

21. The combination with a rolling mechanism, of a holder having a plurality of compartments, a suction-carrier having a plurality of operating-surfaces varying in area, and means for moving the carrier so as to bring the surfaces of the carrier into discharging position with respect to the rolling mechanism, substantially as described.

22. The combination with a rolling mechanism, of a holder having a plurality of compartments, means for maintaining the material at a substantially constant level in the compartments, a suction-head having a plurality of operating-surfaces, one for each compartment, the surfaces varying in area, and means for moving the head from the holder to the rolling mechanism, substantially as described.

23. The combination with a rolling mechanism, of a holder having a plurality of compartments, a suction-head having a plurality of operating-surfaces differing in area, means for moving the head from the holder to the rolling mechanism, and a discharging device coöperating with the surfaces, substantially as described.

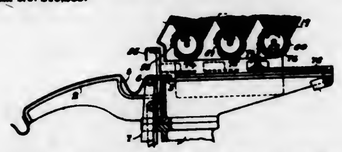
24. The combination with a rolling mechanism, of a holder having a plurality of compartments, a suction-head having a plurality of operating-surfaces differing in area, means for moving the head from

the holder to the rolling mechanism, and a scraper coöperating with the surfaces, substantially as described.

25. The combination with a rolling mechanism, of a holder having a plurality of compartments, means for maintaining the material at a substantially constant level in the compartments, a suction-head having a plurality of operating-surfaces, one for each compartment, the surfaces varying in area, means for moving the head from the holder to the rolling mechanism, and a discharging device coöperating with the surfaces, substantially as described.

26. The combination with a rolling mechanism, of a holder having a plurality of compartments, means for maintaining the material at a substantially constant level in the compartments, a suction-head having a plurality of operating-surfaces, one for each compartment, the surfaces varying in area, means for moving the head from the holder to the rolling mechanism, and a scraper coöperating with the surfaces, substantially as described.

812,220. **FEEDING MECHANISM.** WILLIAM S. LUCKETT, East Orange, N. J., assignor to International Cigar Machinery Company, New York, N. Y., a Corporation of New Jersey. Filed May 28, 1904. Serial No. 210,908.



Claim.—1. The combination with a holder comprising a plurality of compartments, of a suction charge-remover operating to move individual charges varying in volume from the holder, and a transferring device on which the charges are deposited and by which they are carried to a common delivery-point, substantially as described.

2. The combination with a rolling mechanism, of a holder, a suction charge-remover operating to remove a plurality of charges varying in volume from the holder, and a transferring device on which the charges are deposited and by which they are carried to the rolling mechanism, substantially as described.

3. The combination with a holder comprising a plurality of compartments, of suction charge-removing means coöperating with each compartment, means for actuating said charge-removing means to remove charges from the compartments, and a transferring device for the charges, substantially as described.

4. The combination with a holder comprising a plurality of compartments, of suction charge-removing means coöperating with each compartment, means for actuating said charge-removing means to remove charges from the compartments, said charge-removing means being constructed to remove charges of varying volume from the different compartments, and a transferring device for the charges, substantially as described.

5. The combination with a rolling mechanism, of a holder comprising a plurality of compartments, suction charge-removing means coöperating with each compartment, mechanism for actuating said charge-removing means to remove charges from the compartments, and a transferring device for conveying the charges to the rolling mechanism, substantially as described.

6. The combination with a rolling mechanism, of a holder comprising a plurality of compartments, suction charge-removing means coöperating with each compartment, said charge-removing means being constructed to remove charges of different volume from each of the compartments, means for actuating said charge-removing means, and a transferring device which receives the charges from the removing means and carries them to the rolling mechanism, substantially as described.

7. The combination with a holder for granular material, of a rotating suction-cylinder operating in the holder and acting to remove charges therefrom, substantially as described.

8. The combination with a holder for granular material, of a charge-remover comprising a plurality of rotary suction-cylinders operating in the holder and acting to remove charges therefrom, and operating means for the cylinders, substantially as described.

9. The combination with a holder comprising a plurality of compartments, of a charge-remover including a rotary suction-cylinder for each compartment, and means for operating the cylinders, substantially as described.

10. The combination with a holder, of a charge-remover comprising a plurality of rotary suction-cylinders having varying operating areas, and means for operating the cylinders, substantially as described.

11. The combination with a holder having a plurality of compartments, of a charge-remover comprising a plurality of rotary suction-cylinders, one for each compartment, said cylinders having varying operating areas, and means for operating the cylinders, substantially as described.

12. The combination with a rolling mechanism, of a holder, a charge-remover comprising a plurality of rotary suction-cylinders, operating means for the cylinders, and a transferring device for receiving the charges from the cylinders and delivering them to the rolling mechanism, substantially as described.

13. The combination with a rolling mechanism, of a holder comprising a plurality of compartments, of a charge-remover including a rotary suction-cylinder for each compartment, means for operating the cylinders, and a transferring device for receiving the charges from the cylinders and delivering them to the rolling mechanism, substantially as described.

14. The combination with a rolling mechanism, of a holder, a charge-remover comprising a plurality of rotary suction-cylinders having varying operating areas, means for operating the cylinders, and a transferring device for receiving the charges from the cylinders and delivering them to the rolling mechanism, substantially as described.

15. The combination with a rolling mechanism, of a holder having a plurality of compartments, of a charge-remover comprising a plurality of rotary suction-cylinders, one for each compartment, said cylinders having varying operating areas, means for operating the cylinders, and a transferring device for receiving the charges from the cylinders and delivering them to the rolling mechanism, substantially as described.

16. The combination with a holder, of a charge-remover comprising a plurality of rotary suction-cylinders, a carrier, and means for reciprocating the carrier beneath the cylinders to receive the charges successively therefrom, substantially as described.

17. The combination with a holder, of a charge-remover comprising a plurality of rotary suction-cylinders having varying operating areas, a carrier, and means for reciprocating the carrier beneath the cylinders to receive the charges successively therefrom, substantially as described.

18. The combination with a rolling mechanism, of a holder, a charge-remover comprising a plurality of rotary suction-cylinders having varying operating areas, a carrier, and means for reciprocating the carrier beneath the cylinders to receive the charges successively therefrom and carry them to the rolling mechanism, substantially as described.

19. The combination with a rolling mechanism, of a carrier, means for causing successive charges of varying volume to be deposited on the carrier, means for moving the carrier with respect to the rolling mechanism, and delivery means, substantially as described.

20. The combination with a rolling mechanism, of a carrier, means for depositing charges of tobacco varying in volume on the carrier, means for moving the carrier into coöperative relation with the rolling mechanism, and delivery means, substantially as described.

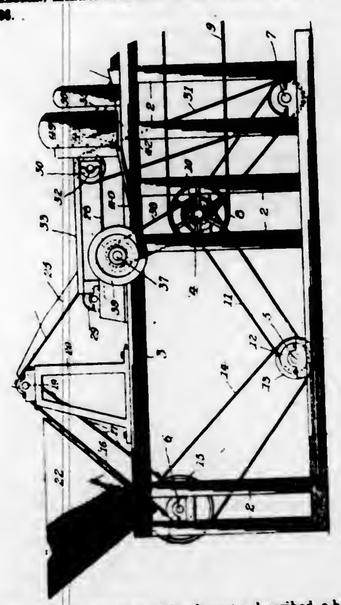
21. The combination with a rolling mechanism, of a carrier, means for depositing charges of tobacco varying in volume on the carrier, means for moving the carrier into coöperative relation with the rolling mechanism, and a scraper for removing the charges from the carrier, substantially as described.

22. The combination with a rolling mechanism, of a holder, a suction operating charge-remover operating to remove charges of varying volume from the holder, a carrier on which charges are successively deposited, means for moving the holder into coöperative relation with the rolling mechanism, and delivery means, substantially as described.

23. The combination with a rolling mechanism, of a holder, charge-removing means comprising a plurality of rotary suction-cylinders having operating-surfaces of varying areas, whereby they remove charges of varying volume, a carrier, means for moving the carrier beneath the cylinders whereby the charges are successively deposited on the carrier, and for moving the carrier into coöperative relation with the rolling mechanism, and delivery means, substantially as described.

24. The combination with a rolling mechanism, of a holder, charge-removing means comprising a plurality of rotary suction-cylinders having operating-surfaces of varying areas, whereby they remove charges of varying volume, a carrier, means for moving the carrier beneath the cylinders whereby the charges are successively deposited on the carrier and for moving the carrier into coöperative relation with the rolling mechanism, and a scraper for removing the charges from the carrier, substantially as described.

812,221. **MACHINE FOR USE IN PACKING BISCUITS.** ARTHUR MAGNAN, Montreal, Canada. Filed Mar. 13, 1905. Serial No. 249,966.



Claim.—1. In a machine of the character described, a hopper, a conveyer, a gravity-chute, a plurality of successively-operable, gravity-stops, oppositely-beveled slides adapted to actuate said stops, and a reciprocatory plunger.

2. In a machine of the character described, a hopper, a conveyer, a gravity-chute, a plurality of intermittently-reciprocatory gravity-stops projecting into said chute, oppositely-beveled slides adapted to lift said stops, and a reciprocatory plunger.

3. In a machine of the character described, a hopper, a yieldable flap near the discharge-orifice thereof, a conveyer, a gravity-chute, a plurality of independently-reciprocatory gates coöperating therewith, slidable and oppositely-beveled members adapted to lift said gravity-operable gate, and a reciprocatory plunger.

4. In a machine of the character described, a hopper, a conveyer, an inclined chute, a belt adapted to travel at less speed than said conveyer, a second chute, gravity-stops projecting into said second chute, oppositely-beveled slides for lifting said stops, and a stacker.

5. In a machine of the character described, a hopper, a conveyer, an inclined chute, a belt therebeyond, a second inclined chute, gravity-operable stops in said chute, reciprocatory means for intermittently lifting said stops, a feed-table, and a stacker operable in conjunction therewith.

6. In a machine of the character described, a hopper, a conveyer, an inclined chute, stops in said chute, means for reciprocating said stops, a feed-table, a stacker, and means operable from the stop-actuating means for actuating said stacker.

7. In a machine of the character described, a hopper, a conveyer, an inclined chute, a belt adapted to travel at a less speed than said conveyer, a second chute, reciprocatory stops operable in series, and independently adapted to project into said second chute, means for operating said stops, and plungers actuated by the stop-operating means.

8. In a machine of the class described, a hopper, a conveyer, an inclined chute, intermittently-operable gravity-stops, reciprocatory plungers, and slidable members adapted to impinge said plungers and to lift said stops.

9. In a machine of the class described, a hopper, a conveyer, an inclined chute, a belt adapted to travel at a less speed than said conveyer, a chute therebeyond, stops in said last-mentioned chute, a plunger, and a slidable member adapted to lift said stops and to actuate said plunger.

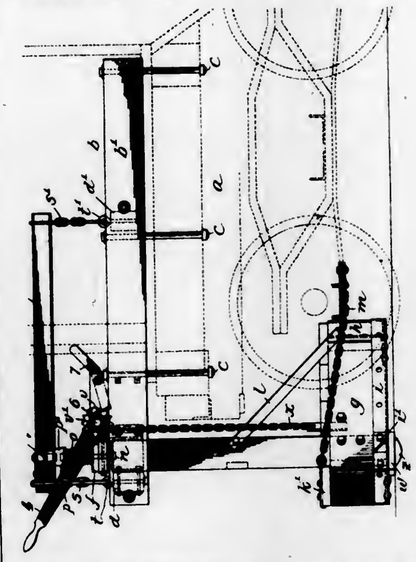
10. In a machine of the class described, a hopper, a conveyer, an inclined chute, a belt adapted to travel at less speed than said conveyer, an inclined chute therebeyond, stops in said last chute, a feed-table, spring-actuated gripe on said table, and a stacker adapted to spread said gripe.

11. In a machine of the character described, a conveyer, an inclined chute leading therefrom, a belt, a second chute therebeyond, a plurality of vertically-reciprocatory gates adapted to enter said chute, slides for actuating said gates, a feed-table divided into longitudinal channels, spring-actuated engaging members projecting into said channels, and plungers adapted to be projected into said channels, said plungers being actuated by said slides.

12. In a machine of the character described, feeding means, an inclined chute, stops in said chute, means for reciprocating said stops, and a stacker comprising spring-actuated guides and reciprocatory plunger.

13. In a machine of the character described, feeding means, an inclined chute, stops operable in series in said chute, a stacker comprising spring-actuated guides and reciprocatory plunger, and a reciprocatory member adapted to operate said stops and said plunger.

812,222. **RAILWAY BALLAST-PLOW.** OTTO W. MEISSNER, Chicago, Ill., assignor to Rodger Ballast Car Company, Chicago, Ill., a Corporation of Illinois. Filed Nov. 18, 1905. Serial No. 288,080.



Claim.—1. The combination with a railway ballast-car of a framework secured to the rear end thereof, comprising side and end bars and angle-straps forming vertical passage-ways, a plow, standards rigidly secured to the plow and passing through the vertical passage-ways in the framework, and means for adjusting the standards.

2. The combination with a railway ballast-car of a framework secured to the rear end thereof, a plow, and cushioned means for supporting the plow in the framework.

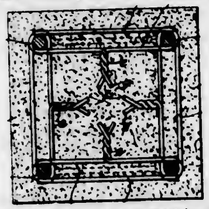
3. The combination with a railway ballast-car of a framework secured to the rear end thereof having vertical passage-ways therethrough, a plow, standards secured to the plow passing through the vertical passage-ways, a cross-piece connecting the standards above the framework, a fulcrum-bolt having a fulcrum member mounted on the cross-piece, a spring interposed between the fulcrum member and the cross-piece, and a lever fulcrumed in the fulcrum member and connected to the framework at its ends.

4. The combination with a railway ballast-car of a framework, a plow mounted for vertical movement in the framework, cushioned means detachably connected to the framework for securing the plow

in operative position, and means for raising and lowering the plow when the securing means is released.

5. The combination with a railway ballast-car of a framework comprising side and end bars, angle-straps mounted on the side and end bars and forming passage-ways therewith, a plow having standards mounted in the passage-ways, a shaft journaled in the framework, flexible connections between the shaft and plow, means for rotating the shaft, a ratchet-wheel on the shaft, and a pawl on the framework engaging the ratchet.

812,223. CONCRETE PILE, PILLAR, &c. GUSTAVE L. MOUCHEL, London, England. Filed Apr. 3, 1905. Serial No. 253,569.



Claim.—1. A concrete structure comprising lengths of metal embedded in concrete, struts between said lengths of metal, and links formed of wire twisted on itself at the side thereof, and projecting ends to said links, substantially as described.

2. A concrete structure comprising lengths of metal embedded in concrete, struts between said lengths of metal and links formed of wire twisted on itself at the side thereof, projecting ends to said links, said projecting ends lying toward the center of the structure, substantially as described.

3. A reinforcing device for concrete structures having embedded rods therein, comprising an elongated link the ends of which are adapted to fit over such rods so as to tie them together, and said link being formed of wire the ends of which are brought together at one side of the link and are twisted around each other and extend in a direction away from the link to form a projecting part of the link.

4. A reinforcing device for concrete structures having embedded rods therein, comprising an elongated link the ends of which are adapted to fit over such rods so as to tie them together, and said link being formed of wire the ends of which are brought together at one side of the link and are twisted around each other and extend in a direction away from the link to form a projecting part of the link, the projecting part being in the plane of the link.

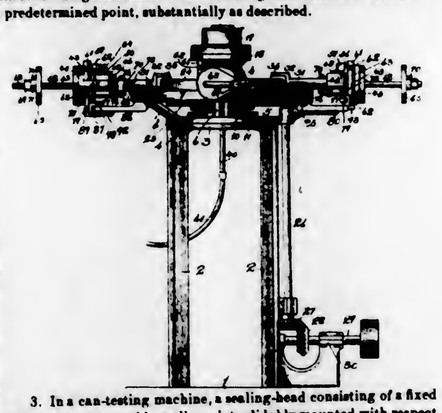
5. A concrete pile comprising lengths of metal embedded in concrete, struts between said lengths of metal, and links formed of wire twisted on itself at the side thereof, projecting ends to said links, said projecting ends lying toward the center of the pile, substantially as described.

6. A concrete beam comprising lengths of metal embedded in concrete, struts between said lengths of metal and links formed of wire twisted on itself at the side thereof, projecting ends to said links, said projecting ends lying toward the center of the beam, substantially as described.

812,224. CAN-TESTING MACHINE. CHARLES B. MCDONALD, Chicago, Ill. Filed Sept. 11, 1905. Serial No. 277,982.

Claim.—1. In a can-testing machine, a sealing-head provided with a fixed sealing-plate and a relatively movable sealing-plate and provided with air-passages opening through the fixed sealing-plate for admitting pressure to a can held between the plates, a slidable rod upon which the movable sealing-plate is mounted, mechanism for moving the slidable rod, a flexible diaphragm in communication with the air-passage through the sealing-head, a plunger, a catch-finger adapted to hold the plunger raised when the diaphragm is in one position and adapted to allow the plunger to fall when the diaphragm is in another position, a cam adapted to actuate the rod-moving mechanism to discharge perfect cans at a predetermined point, a trip-lever adapted to be contacted and thrown by the plunger when the latter is actuated by the leakage of air from an imperfect can, a cam movable with the trip-lever and adapted when moved to actuate the rod-moving mechanism to discharge an imperfect can at a predetermined point, substantially as described.

2. In a can-testing machine, the combination of a revoluble plate having a plurality of sealing-heads radially projecting therefrom, each of the sealing-heads having a fixed sealing-plate and a relatively movable sealing-plate for holding and sealing the cans between the plates, a slidable rod upon which the movable sealing-plate is mounted, mechanism for sliding the rod to lock and release the cans, a diaphragm adapted to be actuated by the pressure admitted to the cans, a plunger adapted to be held in one position when full pressure is exerted on the diaphragm, and adapted to be moved to a different position when the reduced pressure of a leaky can is exerted on the diaphragm, a trip-lever adapted to be contacted and thrown by the plunger when in one position, a cam-finger connected and movable with the trip-lever and adapted when moved to actuate the mechanism controlling the slidable rod to discharge one kind of can at a predetermined point, and a cam adapted to actuate the mechanism controlling the slidable rod to discharge the other class of cans at a predetermined point, substantially as described.



3. In a can-testing machine, a sealing-head consisting of a fixed sealing-plate, a movable sealing-plate slidably mounted with respect to the fixed sealing-plate, an air-passage opening through the fixed sealing-plate and adapted to discharge compressed air into a can, a diaphragm in communication with the air-passage, a stud with a beveled end adapted to be raised and lowered by the movements of the diaphragm, a catch-finger provided with a beveled end adapted to abut against the beveled end of the stud, a plunger provided with a shoulder adapted to be engaged by the catch-finger to hold the plunger in raised position when pressure is exerted on the diaphragm to raise the stud and outwardly project the catch-finger, means actuated by the plunger when in lowered position for discharging imperfect cans at a predetermined point, and means for discharging perfect cans at a predetermined point, substantially as described.

4. In a can-testing machine, a sealing-head consisting of a fixed sealing-plate, a movable sealing-plate slidably mounted with respect to the fixed sealing-plate, an air-passage opening through the fixed sealing-plate and adapted to discharge compressed air into a can, a diaphragm in communication with the air-passage, a stud with a beveled end adapted to be raised and lowered by the movements of the diaphragm, a catch-finger provided with a beveled end adapted to abut against the beveled end of the stud, a plunger provided with a shoulder adapted to be engaged by the catch-finger to hold the plunger in raised position when pressure is exerted on the diaphragm to raise the stud and outwardly project the catch-finger, a lever for moving the movable sealing-plate, a cam for throwing the lever to discharge perfect cans at a predetermined point, a trip mechanism adapted to be actuated by the projected plunger to throw the lever and discharge imperfect cans at a different predetermined point, substantially as described.

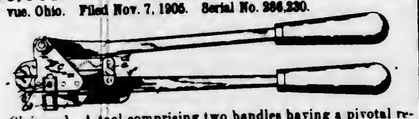
5. In a can-testing machine, a sealing-head adapted to receive and pneumatically seal a can and provided with an air-passage for admitting compressed air to the interior of the can, a flexible diaphragm having one of its surfaces in direct communication with the air-passage leading to the can for normally causing pressure to act on one side only of the diaphragm for outwardly projecting the same, the pressure being equal within the can and against the diaphragm, mechanism actuated by a retraction of the diaphragm due to a decrease of pressure within the can and against the diaphragm for discharging an imperfect can at a predetermined point, means for holding the can against the sealing-head, and mechanism for discharging the perfect cans at a predetermined point, substantially as described.

6. In a can-testing machine, a sealing-head adapted to receive and pneumatically seal a can and provided with an air-passage for admitting compressed air to the interior of the can, a flexible diaphragm having one of its surfaces in direct communication with the air-passage leading to the can for normally causing pressure to act on one side only of the diaphragm for outwardly projecting the same, the pressure being equal within the can and against the diaphragm, a stud carried on the uncompressed side of the diaphragm, and mechanism actuated by the fall of the stud due to the retraction of the diaphragm for discharging the imperfect cans at a predetermined point, means for holding the can against the sealing-head, and mechanism for discharging perfect cans at a predetermined point, substantially as described.

7. In a can-testing machine, a sealing-head adapted to receive and pneumatically seal a can and provided with an air-passage for admitting compressed air to the interior of the can, a flexible diaphragm having one of its surfaces in direct communication with the air-passage leading to the can for normally causing pressure to act on one side only of the diaphragm for outwardly projecting the same, the pressure being equal within the can and against the diaphragm, a stud resting upon the outer side of the diaphragm, a spring surrounding the stud and adapted to equalize the pressure on both sides of the diaphragm, and mechanism actuated by the retraction of the stud for discharging the imperfect cans at a predetermined point, means for holding the can against the sealing-head, and mechanism for discharging the perfect cans at a predetermined point, substantially as described.

8. In a can-testing machine, a sealing-head adapted to receive and pneumatically seal a can and provided with an air-passage leading to the interior of the can, a diaphragm having its inner face only in direct communication with the air-passage for receiving thereon a pressure equal to the pressure within the can, a plunger adapted to be actuated by movements of the diaphragm due to a decrease of pressure thereon caused by leakage from the can, and mechanism actuated by the plunger for releasing an imperfect can at a predetermined point, means for holding the can against the sealing-head, and mechanism for releasing perfect cans at a different predetermined point, substantially as described.

812,225. BOLT-CLIPPER AND PUNCH. JOHN L. PAINTER, Bellevue, Ohio. Filed Nov. 7, 1905. Serial No. 286,230.



Claim.—1. A tool comprising two handles having a pivotal relation to each other, one of said handles having a fixed cutting-jaw at one end thereof, a movable jaw arranged between said handles, and means for operating said jaw, whereby it will be given an oblique movement relative to the fixed jaw.

2. A tool comprising two handles having a pivotal relation to each other, one of said handles having a fixed cutting-jaw and a punch-socket at one end thereof, a punch slidably mounted in said jaw, a movable jaw arranged between said handles, means for operating said jaw whereby it will be given an oblique movement relative to the fixed jaw and means for lifting said punch.

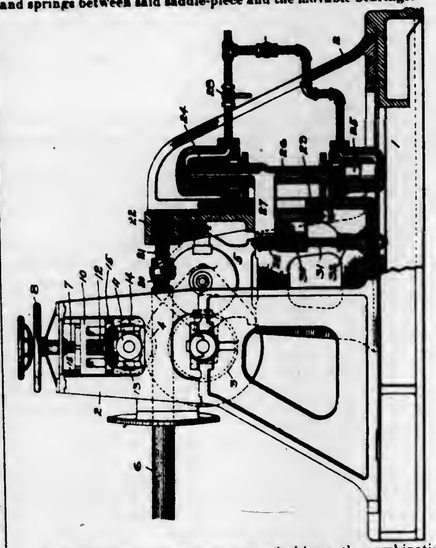
3. A tool comprising an upper handle and a lower handle having a pivotal relation to each other said lower handle having a fixed cutting-jaw at one end thereof, a movable jaw arranged between said handles and pivotally connected to the lower handle, means for operating said jaw by frictional contact with the upper handle, and a spring bearing against said movable jaw and lift.

4. A tool comprising an upper handle and a lower handle having a pivotal relation to each other, said lower handle having a fixed cutting-jaw and a punch-socket at one end thereof, a movable jaw arranged between said handles, said jaw adapted to move obliquely relative to the fixed jaw, means for operating said jaw from the upper handle said means comprising a roller-bearing, and means for lifting said punch.

5. A tool comprising an upper movable element and a lower fixed element, said fixed element having a cutting-jaw, and punch-socket arranged therein, a punch slidably mounted in said socket, a spring adapted to lift said punch, a movable jaw mounted between said elements and adapted to depress said punch said jaw pivoted on said fixed element and connected with said movable element with an antifrictional bearing therebetween.

812,226. DEVICE FOR OPERATING MANDREL-BARS. PETER C. PATTERSON, McKeesport, Pa., assignor to National Tube Company, Pittsburg, Pa., a Corporation of New Jersey. Filed Feb. 4, 1904. Serial No. 192,080.

Claim.—1. In apparatus for operating mandrel-bars, the combination with the housings, of a pair of grooved rolls mounted therein, movable bearings for one of said rolls, an adjustable saddle-piece, and springs between said saddle-piece and the movable bearings.



2. In apparatus for operating mandrel-bars, the combination with the housings, of a pair of grooved rolls mounted therein, movable bearings for one of said rolls, trunnions on said bearings, sliding bearings movable vertically in said housings and provided with seats for said trunnions, and adjusting means for said bearings.

3. In apparatus for operating mandrel-bars, the combination with the housings, of a pair of grooved rolls mounted therein, movable bearings in one of said rolls, trunnions on said bearings, sliding bearings vertically movable in said housings and provided with seats for said trunnions, adjusting means for said bearings, and springs between said bearings and adjusting means.

4. In apparatus for operating mandrel-bars, the combination of housings, positively-driven grooved rolls mounted therein, an abutment to the rear of said rolls and arranged to move vertically, and power mechanism connected to said abutment and arranged to positively draw the same downwardly, and to automatically raise the same.

5. In apparatus for operating mandrel-bars, the combination of housings, positively-driven grooved rolls mounted therein, a vertically-movable abutment to the rear of said rolls, and a vertical reciprocating motor connected to said abutment and arranged to positively draw the same downwardly and to automatically raise the same.

6. In apparatus for operating mandrel-bars, the combination with positively-driven grooved rolls, of a sliding abutment to the rear thereof, differential power-cylinders, rigidly-connected pistons for said cylinders, and connections from said pistons to said abutment for moving the same.

7. In apparatus for operating mandrel-bars, the combination with positively-driven grooved rolls, of a vertically-movable abutment to the rear thereof, vertically-arranged differential power-cylinders, and connections between the same and said abutment for raising and lowering the same

8. In apparatus for operating mandrel-bars, the combination with driven grooved rolls of a vertically-movable abutment to the rear thereof, a motor connected to said abutment for raising and lowering the same, a guide-rod passing through an opening in said abutment, and cushioning-springs on said rod both above and below said abutment.

9. In apparatus for operating mandrel-bars, the combination with driven grooved rolls of a vertically-movable abutment to the rear thereof, a pair of vertically-arranged power-cylinders of different sizes, a piston-rod therefor, connections between the piston-rod and said abutment, means for maintaining constant pressure in the smaller of said cylinders, and means for admitting pressure to, and releasing same from, the larger of said cylinders.

812,227. **ELASTIC METAL FELLY.** ALBERT PROST, Hanover, Germany. Filed Jan 12, 1905. Serial No. 240,778.

Claim.—1. An elastic metallic felly for vehicle-wheels comprising in combination a concave plate *b* and a curved plate leading inwardly from one of the edges of said concave plate.

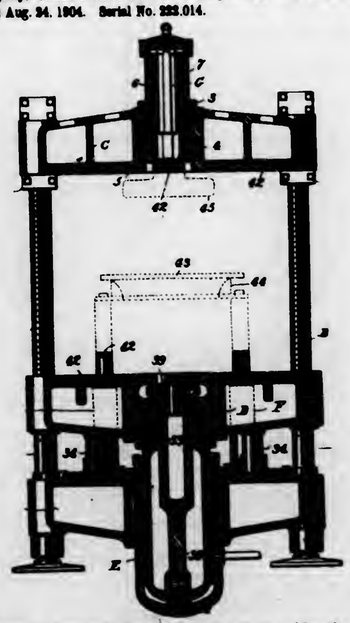
2. An elastic metallic felly for vehicle-wheels comprising in combination a concave plate *b* and a curved plate leading inwardly from one of the edges of said concave plate and a cylindrical plate bridging said concave plate.

3. An elastic metallic felly for vehicle-wheels comprising in combination a concave plate *b* and a curved plate leading inwardly from one of the edges of said concave plate and an annular rod supporting the other edge of said concave plate.

4. An elastic metallic felly for vehicle-wheels comprising a concave plate *b*, a convex plate *c* and a curved plate extending from one edge of plate *b* to one edge of plate *c*.

5. An elastic metallic felly for vehicle-wheels comprising a concave plate *b*, a convex plate *c* and a curved plate extending from one edge of plate *b* to one edge of plate *c* and cylindrical plates *d e* bridging said plates *b c* respectively.

812,228. **FLUID-PRESSURE METAL-WORKING MACHINE.** CASIMIR VON PHILP, Bethlehem, Pa., assignor to The Bethlehem Steel Company, South Bethlehem, Pa., a Corporation of Pennsylvania. Filed Aug. 24, 1904. Serial No. 223,014.



Claim.—1. In a fluid-pressure metal-working machine, the combination with a platen, of a fluid-pressure cylinder and plunger mounted in said platen, a bed-plate, a plurality of jacks upon the bed-plate for supporting the work, and means for moving said jacks with relation to said platen, for the purpose set forth.

2. In a fluid-pressure metal-working machine, the combination with a platen, of a fluid-pressure cylinder mounted thereon, a bed-plate, tracks upon said bed-plate, jacks for supporting the work mounted upon said tracks, and means for moving said jacks along said tracks, for the purpose set forth.

3. In a fluid-pressure metal-working machine, the combination with a platen, of a fluid-pressure cylinder mounted thereon, a bed-plate, tracks upon said bed-plate, jacks for supporting the work mounted upon said tracks, and screw-and-nut connections between said bed-plate and said jacks, for the purpose set forth.

4. In a fluid-pressure metal-working machine, the combination with a platen, of a fluid-pressure cylinder mounted thereon, a bed-plate, radial tracks upon said bed-plate, jacks for supporting the work mounted upon said tracks, and means for moving said jacks along said tracks, for the purpose set forth.

5. In a fluid-pressure metal-working machine, the combination with a platen, of a fluid-pressure cylinder mounted thereon, a bed-plate, radial tracks upon said bed-plate, jacks for supporting the work mounted upon said tracks, and screw-and-nut connections between said bed-plate and said jacks, for the purpose set forth.

6. In a fluid-pressure metal-working machine, the combination with a platen, of a fluid-pressure cylinder mounted thereon, a bed-plate, tracks upon said bed-plate, fluid-pressure jacks for supporting the work mounted upon said tracks, and means for moving said jacks along said tracks, for the purpose set forth.

7. In a fluid-pressure metal-working machine, the combination with a platen, of a fluid-pressure cylinder mounted thereon, a bed-plate, tracks upon said bed-plate, fluid-pressure jacks for supporting the work mounted upon said tracks, and screw-and-nut connections between said bed-plate and said jacks, for the purpose set forth.

8. In a fluid-pressure metal-working machine, the combination with a platen, of a fluid-pressure cylinder mounted thereon, a bed-plate, radial tracks upon said bed-plate, fluid-pressure jacks for supporting the work upon said tracks, and means for moving said jacks along said tracks, for the purpose set forth.

9. In a fluid-pressure metal-working machine, the combination with a platen, of a fluid-pressure cylinder mounted thereon, a bed-plate, radial tracks upon said bed-plate, fluid-pressure jacks for supporting the work mounted upon said tracks, and screw-and-nut connections between said bed-plate and said jacks, for the purpose set forth.

10. In a fluid-pressure metal-working machine, the combination with a bed-plate, of upper and lower platens supported thereon, a fluid-pressure working cylinder mounted in said upper platen, a central plunger for supporting the work, and means for raising said plunger, for the purpose set forth.

11. In a fluid-pressure metal-working machine, the combination with a bed-plate, of upper and lower platens supported thereon, a fluid-pressure cylinder mounted in the upper platen, jacks for supporting the work mounted at a distance from the center, and a central plunger, for the purpose set forth.

12. In a fluid-pressure metal-working machine, the combination with a bed-plate, of upper and lower platens supported thereon, a fluid-pressure cylinder having its plunger connected to said lower platen, said plunger being hollow, and a second plunger acting as a support for the work mounted within the first plunger, for the purpose set forth.

13. In a fluid-pressure metal-working machine, the combination with a bed-plate, of upper and lower platens supported thereon, a fluid-pressure cylinder having its plunger connected to said lower platen, said plunger being hollow, and a second plunger acting as a support for the work mounted within the first plunger and movable independently thereof, for the purpose set forth.

14. In a fluid-pressure metal-working machine, the combination with a bed-plate, of upper and lower platens mounted thereon, a fluid-pressure cylinder mounted in the upper platen, a fluid-pressure cylinder having its plunger connected to the lower platen, said plunger being hollow, fluid-pressure jacks for supporting the work mounted upon said bed-plate and extending above the lower platen, and a central plunger for supporting the work mounted within the aforesaid plunger, for the purpose set forth.

15. In a fluid-pressure metal-working machine, the combination with a bed-plate, of upper and lower platens supported thereon, a fluid-pressure working cylinder slidably mounted in a slot in said upper platen, said cylinder having lugs bearing upon the top of said platen, and other lugs entering grooves in the sides of said slot, said grooves being located between the top and bottom of said upper platen, for the purpose set forth.

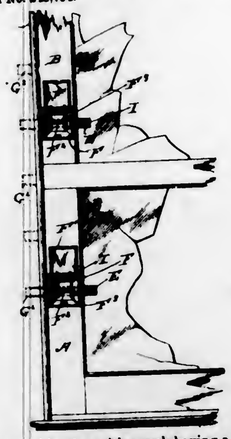
16. In a fluid-pressure metal-working machine, the combination with a bed-plate, of upper and lower platens supported thereon, a fluid-pressure working cylinder slidably mounted in a slot in said upper platen, said cylinder having lugs bearing upon the top of said platen, other lugs entering grooves in the sides of said slot, said grooves being located between the top and bottom of said upper platen, and set-screws carried by the lugs bearing upon the top of the platen and adapted to engage with said platen, for the purpose set forth.

17. In a fluid-pressure metal-working machine, the combination with a bed-plate, of upper and lower platens supported thereby, a fluid-pressure working cylinder mounted in the upper platen, said cylinder comprising an outer cylinder, a plunger therein, and a guide arranged within the plunger for preventing rotation of said plunger with relation to said outer cylinder, for the purpose set forth.

18. In a fluid-pressure metal-working machine, the combination with a bed-plate, of upper and lower platens supported thereby, and a fluid-pressure working cylinder mounted in the upper platen, said cylinder comprising an outer cylinder, a hollow plunger therein, a guide fixed to the head of said cylinder and extending within said plunger, said guide having longitudinal grooves, and lugs upon said plunger extending within said grooves, for the purpose set forth.

19. A fluid-pressure cylinder comprising an outer cylinder, a hollow plunger therein, a guide projecting from the cylinder-head within said plunger, said guide having longitudinal grooves, and lugs secured to said plunger and projecting into said grooves, for the purpose set forth.

812,229. **SASH-LOCK.** JAMES POWER, Methuen, Mass. Filed Mar. 7, 1905. Serial No. 248,784.



Claim.—The combination with a sash having a horizontal bore and a recess communicating with said bore, of a sleeve fitting in said recess provided with horizontal and vertical slots communicating with each other, a box fitting in said recess having slots formed in its rear wall, corresponding with the slots of the sleeve, a bolt provided with annular ribs arranged in said sleeves, a spring arranged at one end of the sleeve, a pin secured to the bolt extending through the slots of the sleeve and box, and provided with a head, and a hinged cover adapted to close said box, for the purpose described.

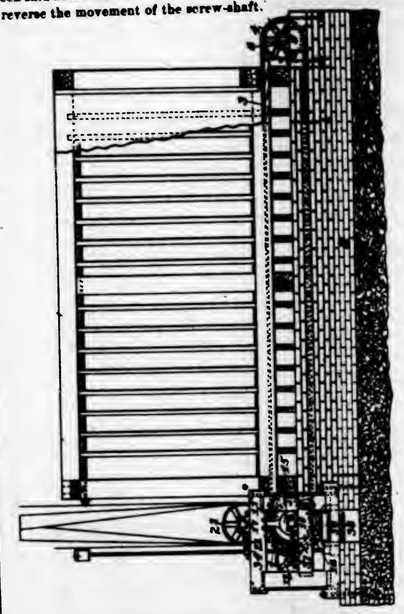
812,230. **EMPTYING APPARATUS FOR CLAY-BINS.** CHARLES W. RAYMOND, Dayton, Ohio. Filed Apr. 6, 1905. Serial No. 254,147.

Claim.—1. In an emptying apparatus for storage-bins, a feed chain or carrier revolving over the floor of the bin, means for imparting lateral movement to said feed-chain during its revolving movement, and automatic means for reversing the lateral movements during the revolving movement.

2. In an emptying apparatus for bins, a feed-chain revolving over the floor of the bin, sliding sprocket-wheels upon which said feed-chain is mounted, a yoke engaging one of said sprocket-wheels, a screw-shaft upon which the said yoke is mounted, and means for reversing the direction of rotation of the screw-shaft to reverse the lateral movements of the feed-chain, through the yoke.

3. In an emptying apparatus for bins, the combination with a bin, of a feed-chain revolving over the floor thereof, sprocket-wheels upon which said feed-chain is mounted, shafts upon which said sprocket-wheels are slidingly mounted, a yoke engaging one of said sprocket-wheels, a screw-shaft upon which said yoke is mounted, clutch and pulley mechanism on said screw-shaft, and means for throwing said clutch to reverse the movements of the screw-shaft and therewith the yoke.

4. In an emptying apparatus for storage-bins, a clay-bin, a feed-chain revolving over the floor of said bin, laterally-sliding sprocket-wheels upon which said chain is mounted, a controlling-yoke engaging one of said sprocket-wheels, a screw-shaft upon which said yoke is mounted, clutch and pulley devices on said screw-shaft, means for rotating the pulleys in opposite directions, arms engaging said yoke at the limit of its movement in either direction, and mechanism between said arms and said clutch devices whereby the clutch is shifted to reverse the movement of the screw-shaft.



5. In an emptying apparatus for storage-bins, a bin, a feed-chain revolving over the floor of said bin, laterally-movable sprocket-wheels supporting said feed-chain, a controlling-yoke engaging one of said sprocket-wheels, a screw-shaft upon which said yoke is mounted, clutch and pulley mechanism mounted upon said screw-shaft and whereby the direction of rotation of the screw-shaft is reversed, means for reversing said direction at the limit of the movement of the yoke in either of its lateral directions, and an off-conveyer to receive from the feed chain or carrier.

812,231. **PULVERIZER.** GEORGE RAYMOND, Chicago, and JOHN H. FINLAY, Warsaw, Ill. Filed July 26, 1902. Renewed May 31, 1905. Serial No. 263,182.

Claim.—1. In a pulverizing-mill, the combination with a rotating drum having pockets, of peripheral openings in said pockets,

peripheral scoops adapted to guide material to said openings, tumblers confined within said pockets, and a screen surrounding said drum and rotating therewith, substantially as described.

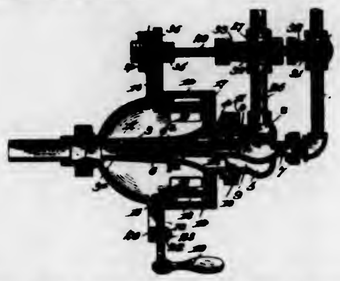
2. In a pulverizing-mill, the combination with a rotating drum, of pockets in said drum, peripheral openings in said pockets, tumbler-balls confined within said pockets, said pockets being provided with inclines 15 and sockets 16, whereby said balls are carried in said sockets during the upward part of their revolution and with raceways to guide the motion of said tumblers, and a cylindrical screen surrounding said drum and rotating therewith, substantially as described.

3. In a pulverizing-mill, the combination with a rotating drum, of pockets in said drum, peripheral openings in said pockets, tumbler-balls confined within said pockets, said pockets being provided with inclines 15 and sockets 16, whereby said balls are carried in said pockets during the upward part of their revolution and with raceways to guide the motion of said tumblers, a cylindrical screen surrounding said drum and rotating therewith, and scoops adapted to guide material to said openings, substantially as described.

4. In a pulverizing-mill, the combination with hub portions 7 of similar drum-sections 8, provided with pockets 10, said drum-sections being displaced angularly, and tumblers confined within said pockets, substantially as described.

5. In a pulverizing-mill, the combination with hub portions 7 of similar drum-sections 8, provided with pockets 10, said drum-sections being displaced angularly, wooden wedges whereby said drum-sections are keyed to said hub portions, and tumblers confined within said pockets, substantially as described.

812,232. **INJECTOR.** LEVI RHODES, Spokane, Wash., assignor to Motor Traction Company, Spokane, Wash., a Corporation. Filed Apr. 21, 1904. Serial No. 204,283.

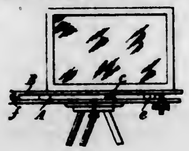


Claim.—1. In an injector, the combination with the air-nozzle having air-admission ports, of a revoluble shutter for controlling said ports, means for operating the shutter an oil-nozzle projecting within said air-nozzle, an oil-inlet having a valve, a steam-nozzle projecting within said oil-nozzle, a steam-inlet having a valve, and means operated by the shutter to simultaneously control said valves, substantially as described.

2. In combination with a rotary air-controlling shutter of an injector having an oil and a steam inlet, of a single valve-stem for controlling both of said inlets, and means whereby the operation of the shutter will operate said stem, substantially as and for the purpose set forth.

3. In an injector, the combination with an air, an oil, and a steam nozzle, of a rotary shutter for controlling the admission of air to the air-nozzle, having a rack, a pinion operated by said rack, having a screw-threaded bore, a valve-stem for controlling the flow of both oil and steam, having screw-threads thereon adapted to gear with the threaded bore of said pinion, substantially as and for the purpose set forth.

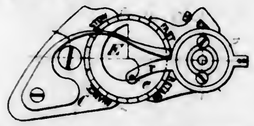
812,233. **TRIPOD-HEAD.** MONTAGUE C. ROCK, Sunnyside, England. Filed May 16, 1905. Serial No. 260,660.



Claim.—1. In a device for the purpose set forth, the combination of a plate member adapted to be secured to the stand or tripod, a second plate member adapted to hold a camera and furnished at one end with clip-pieces between which and said end the tripod plate member may be introduced when the plates are set at right angles, a stop on the tripod plate member, means for holding the camera plate member up to this stop when the plate members are at right angles and means for securing the plate members together when superposed in parallel planes, substantially as described.

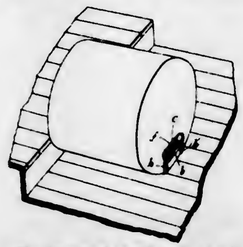
2. In a device for the purpose set forth, the combination of the plate member A adapted to be secured to the stand or tripod and having at one end the retaining-flange *g* and at the other end the slot *i*, and the plate member B adapted to hold a camera and having one end adapted to engage beneath said flange *g* and the other end provided with the clip-pieces *l* and the screw and nut *k*, the whole arranged and adapted to operate substantially as described and illustrated.

812,234. **WATCH.** HERMANN ROOST, St. Imier, Switzerland. Filed Jan. 12, 1904. Serial No. 188,680.



Claim.—In a watch-movement, the combination with a cock having a circular recess formed in its upper sufrace, of a disk resting loosely in said recess, which disk has an eccentric opening, a regulator pivoted to said cock and having an arm which extends loosely over said disk, a pin fixed at the end of said arm and extending into the opening in the disk, a spring attached to the cock and bearing against the arm, thereby pressing the pin on the end of the arm against the edge of the opening in the disk, said spring also extending over the upper surface of the disk, said spring and arm holding the disk in the recess the cock having a portion on each side of the recess cut away to afford access to the disk, substantially as set forth.

812,235. **MERCHANDISE-HOOK.** JOSEPH A. A. ROULEAU, St. Cunegonde, Canada, assignor of one-half to Charles Hugh James Bowden, Montreal, Canada. Filed Nov. 24, 1905. Serial No. 288,962.

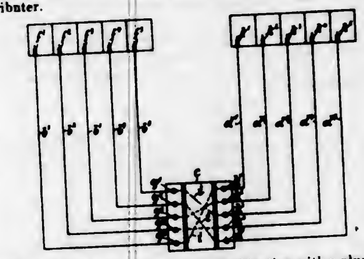


Claim.—1. The improved merchandise-hook consisting of a main bar with a plurality of bent fingers at one side, a handle portion at the opposite side and a guard projection on the bar substantially as described.

2. The improved merchandise-hook consisting of a bearing-bar with a pair of fingers at one side such fingers being disposed with the portions thereof contiguous to the bar in the same plane as the bearing-face of the latter, and the sides of their bent ends toward such bar serrated, and a handle portion upon the side of the bar opposite to the finger and extending in the plane of the said opposite side for the purpose of providing a space between the plane in which the handle lies and the plane of the said bearing-face of the bar substantially as described.

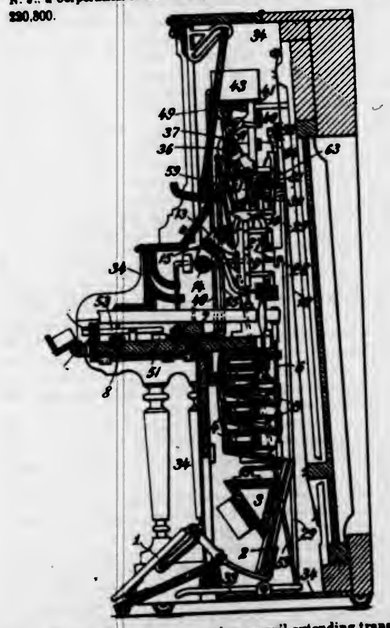
812,236. **JACK-CORD DISTRIBUTER.** BENNO SALMANN, Berlin, Germany. Filed Nov. 16, 1905. Serial No. 287,734.

Claim.—1. In a telephone-exchange, the combination with a plurality of distribution-switchboards each provided with a hearing-plug, of a plurality of connection-switchboards each provided with a jack, a jack-cord distributer comprising two rows of binding-posts or the like, a plurality of cords connecting the hearing-plugs in said plurality of distribution-switchboards with the binding-posts or the like in the one row of said jack-cord distributer, a plurality of jack-cords connecting the jacks in said plurality of connection-switchboards with the binding-posts or the like in the other row of said jack-cord distributer, shiftable cords for connecting at will the several binding-posts or the like of the one row with those of the other row in said jack-cord distributer, and means for fastening the ends of said shiftable cords on the binding-posts or the like in said jack-cord distributer.



2. In a telephone-exchange, the combination with a plurality of distribution-switch-boards each provided with a hearing-plug, of a plurality of connection-switchboards each provided with a jack, a jack-cord distributer comprising two rows of binding-posts or the like, a plurality of cords shiftably connecting the hearing-plugs in said plurality of distribution-switchboards with the binding-posts or the like in the one row of said jack-cord distributer, a plurality of jack-cords shiftably connecting the jacks in said plurality of connection-switchboards with the binding-posts or the like in the other row of said jack-cord distributer, shiftable cords for connecting at will the several binding-posts or the like of the one row with those of the other row in said jack-cord distributer, and means for fastening the ends of said shiftable cords on the binding-posts or the like in said jack-cord distributer.

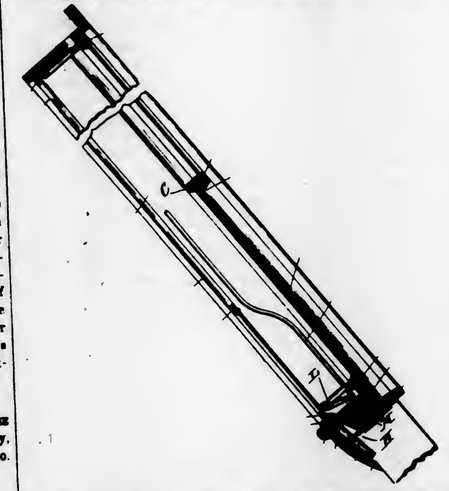
812,237. **TONE-MODULATING DEVICE FOR PIANOS.** JOSE SAMPERE, New York, N. Y., assignor to The Regina Company, Rahway, N. J., a Corporation of New Jersey. Filed Aug. 15, 1904. Serial No. 220,800.



Claim.—1. In a piano, a continuous rail extending transversely of the strings, a sectional rail spaced from said continuous rail and extending parallel therewith, and pneumatically-operated devices for moving the sections of the second-named rail individually, the actuating portions of said devices being arranged between the continuous rail and the sectional rail.

2. In a piano, a continuous rail extending transversely of the strings, a sectional rail spaced from said continuous rail and extending parallel therewith, and pneumatically-operated devices for moving the sections of the second-named rail individually, the actuating portions of said devices being arranged between the continuous rail and the sectional rail, and an operating device for the continuous rail, the actuating portions of said device being located on the side of the said rail opposite to that on which the first-named operating devices are placed.

812,238. **WINDOW-VENTILATOR.** DIEDRICH SCHAFER, Sacramento, Cal. Filed May 3, 1905. Serial No. 258,621.



Claim.—1. In a window-ventilator, a horizontal screen-frame secured to the top rail of the upper sash, and a vertical screen-frame acting in conjunction with said horizontal frame to form an insect and dust proof deflector for the top of the casing, substantially as shown and described.

2. In a window-ventilator, a horizontal screen-frame secured to the top rail of the upper sash, and a vertical screen-frame secured to the free edge of said horizontal frame, substantially as shown and described.

3. In a window-ventilator, a horizontal screen-frame secured to the top rail of the upper sash, a vertical screen-frame secured to the free edge of said horizontal frame, and a housing in the top of the casing to receive said vertical frame, substantially as shown and described.

4. In a window-ventilator, a frame slidably mounted in the window-casing, a screen-frame secured to the lower edge of said frame, a box or casing beneath the window-sill to receive said screen-frame, and a screen-frame secured to the bottom rail of the lower sash to bridge the space between the sash and the first-named frame, substantially as shown and described.

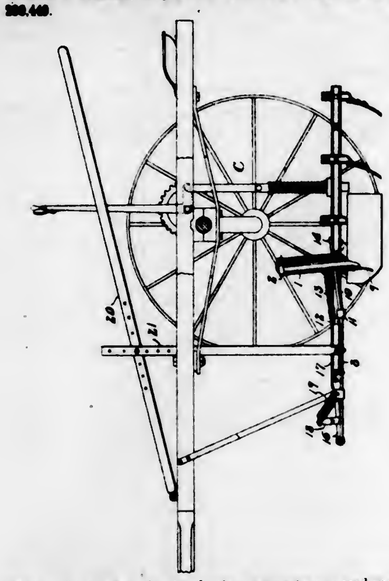
5. In a window-ventilator, a frame slidably mounted in the window-casing, a screen-frame hinged to the lower edge of said frame, a box or casing beneath the window-sill to receive said screen-frame, and a horizontal screen-frame secured to the bottom rail of the lower sash to bridge the space between said sash and the first-named frame, substantially as shown and described.

6. In a window-ventilator, a frame slidably mounted in the window-casing, a screen-frame secured to the lower edge of said frame, a box or casing beneath the window-sill to receive said screen-frame, a screen-frame secured to the bottom rail of the lower sash, a screen-frame hinged to the last-named screen-frame, and grooves in the window-casing to guide said hinged frame, substantially as shown and described.

7. In a window-ventilator, a frame slidably mounted in the window-casing, a screen-frame hinged to the lower edge of said frame, a box or casing beneath the window-sill to receive said screen-frame,

a screen-frame secured to the bottom rail of the lower sash, a screen-frame hinged to the last-named screen-frame, and the window-casing formed with grooves to guide said hinged frame, substantially as shown and described.

812,239. **REPLANTING ATTACHMENT FOR CULTIVATORS.** WILLIAM J. SUMMER, Aripo, Iowa. Filed Dec. 5, 1905. Serial No. 290,449.



Claim.—1. A supporting-bar having an aperture, a seed-receptacle slidably engaging said bar, and bottom members in said receptacle adjacent to the upper and under sides of the bar and having apertures adapted for alternate registry with the aperture in the bar.

2. A supporting-bar having an aperture, a slidably-supported seed-receptacle having apertured bottom members adjacent to the upper and under sides of the bar, spring means for moving the receptacle in a forward direction upon the bar, and an earth-engaging member connected with the receptacle.

3. A supporting-bar, a seed-receptacle slidable thereon, means for limiting the forward and rearward movement of the receptacle, and means for normally forcing the receptacle in a forward direction.

4. A supporting-bar, a seed-receptacle slidable thereon, means for limiting the forward and rearward movement of the receptacle, spring means for normally forcing the receptacle in a forward direction, and a furrow-opener connected with the receptacle for engagement with the earth to anchor said receptacle for rearward movement against the tension of the spring.

5. A hinged supporting-bar, a seed-receptacle slidable thereon, means for limiting the forward and rearward movement of the receptacle, a spring for normally forcing the receptacle in a forward direction, and a furrow-opener connected with the receptacle for engagement with the earth to anchor said receptacle for rearward movement against the tension of the spring.

6. A hinged supporting-bar, spring means for normally elevating the free end of the supporting-bar, a spring-actuated seed-receptacle slidably engaging the supporting-bar, and an earth-engaging blade connected with the receptacle.

7. A supporting-bar having stop-lugs, a seed-receptacle slidably engaging the bar between the lugs, a spring connecting the receptacle with one of the lugs, and an earth-engaging blade upon the receptacle.

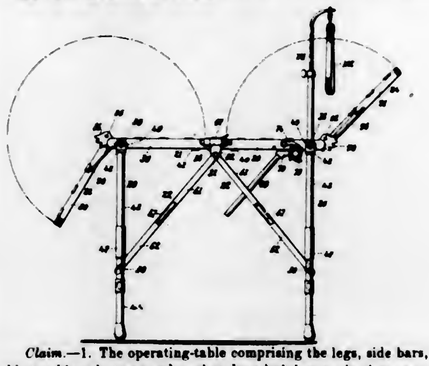
8. A supporting-bar having stop-lugs, a seed-receptacle slidably engaging the bar between the lugs, a spring connecting the receptacle with one of the lugs, an earth-engaging blade connected with the receptacle and having a shank, and a sleeve upon said shank encircling the supporting-bar.

9. A supporting-bar, spring means for normally elevating the free end of said bar, a spring-actuated seed-receptacle slidable upon the bar and having an earth-engaging member, and lever means for depressing the supporting-bar against the tension of the lifting-spring.

10. A bracket having an upright, a supporting-bar hingedly connected with the bracket, a spring connecting the supporting-bar with the upright, a spring-actuated seed-receptacle slidably engaging the supporting-bar and having an earth-engaging member, and lever means for depressing the supporting-bar.

11. A bracket comprising two adjustably-connected members, one of said members being provided with an upright, a supporting-bar hingedly connected with one of the members of the bracket, a spring connecting the supporting-bar with the upright, a spring-actuated seed-receptacle slidably engaging the supporting-bar and having an earth-engaging member, and lever means for depressing the supporting-bar.

812,240. **OPERATING-TABLE.** JOSEPH SCHONTYL, CHRISTIAN JAEGER, and PAUL WALSLEBEN, Brooklyn, N. Y., assignors to David Frank, Brooklyn, N. Y., and John Trounstine, New York, N. Y. Filed Mar. 10, 1903. Serial No. 147,045.



Claim.—1. The operating-table comprising the legs, side bars, table-top hinged at one end, and rack-and-pinion mechanism operable by a crank for raising and lowering said top from its other end, said top being normally set in between said side bars, and said side bars and top being independently composed of hinged sections in end-to-end relation with the pintles of the hinges in line with each other and about on a line with the transverse center of the table so that they may be together folded downwardly and also so that said top may be independently given the position of a double incline for certain operations, combined with foldable means adjacent to the center of the table for, after the table-top has been raised to an inclined position, firmly supporting the hinged end section of said top in its inclined position while the other section of said top is being lowered at its outer end by said rack-and-pinion mechanism to create the double incline, the foldable head and foot frames at the ends of the table and one of which is carried by the free end of said top, and means for adjusting the inclination of said frames; substantially as set forth.

2. The operating-table comprising the legs, side bars, table-top hinged at one end, and rack-and-pinion mechanism operable by a crank for raising and lowering said top from its other end, said side bars and top being independently composed of hinged sections in end-to-end relation with the pintles of the hinges about on a line with the transverse center of the table so that they may be together folded downwardly and also so that said top may be independently given the position of a double incline for certain operations, combined with foldable means adjacent to the center of the table for, after the table-top has been raised to an inclined position, firmly supporting the hinged end section of said top in its inclined position while the other section of said top is being lowered at its outer end by said rack-and-pinion mechanism to create the double incline, the foldable head and foot frames at the ends of the table and one of which is carried by the free end of said top, and means for adjusting the inclination of said frames; substantially as set forth.

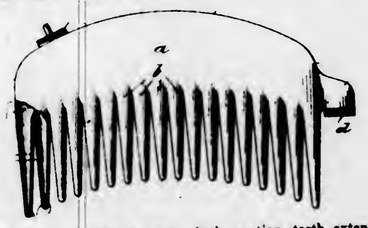
3. The operating-table comprising the side bars, the hinged legs composed of hinged foldable sections, the foldable leg-braces hinged at their upper ends at about the center of said side bars and adapted at their lower ends to be detachably connected to said legs, the table-top hinged at one end, and means for raising and lowering said top from its other end, said side bars and top each being independently composed of sections hinged together at about the transverse center of the table so that they may be together folded downwardly and also so that said top may be independently given the position of a double incline for certain operations, combined with means adjacent to the center of the table for supporting the hinged end section of said top in an upwardly-inclined position while the other section of said top is inclined downwardly, means connected with said side bars for locking their sections together at their joint in horizontal extended position, means connected with the hinged table-top sections for locking them together at their joint in their horizontal extended position, and the head and foot frames at the ends of the table; substantially as set forth.

4. The operating-table comprising the legs, side bars, table-top hinged at one end, and means for raising and lowering said top from its other end, said side bars and top each being independently composed of sections hinged together at about the transverse center of the table so that they may be together folded downwardly and also so that said top may be independently given the position of a double incline for certain operations, combined with means adjacent to the center of the table for supporting the hinged end section of said top in an upwardly-inclined position while the other section of said top is inclined downwardly, means connected with said side bars for locking their sections together at their joint in horizontal extended position, means connected with the hinged table-top sections for locking them together at their joint in their horizontal extended position, and the head and foot frames at the ends of the table; substantially as set forth.

5. The operating-table comprising the side bars, the hinged legs composed of hinged foldable sections, the movable sleeves on said legs to pass over the joint between said sections, and the hinged sectional foldable leg-braces adapted at their lower ends to be detachably connected to said legs and to be locked thereto by the lower edge of said sleeves, combined with the table-top hinged at one end, and means for raising and lowering said top from its other end, said side bars and top being composed of sections hinged together at about the transverse center of the table so that they may be folded; substantially as set forth.

6. The operating-table comprising the side bars, legs, hinged table-top, and means for raising and lowering said top from its free end, combined with the frame hinged at the end of said table-top, and the pawl-and-ratchet mechanism for securing said frame in its desired positions, said mechanism comprising the ratchet-plates 85, the plates 83 constituting a part of said frame and having the recesses 84, the rod 87 whose transverse portions engage said recesses and said ratchet-plates and whose end portions 88 extend along the sides of said frame and then turn inwardly through apertures in said frame, and the pins 90 which afford supports for said end portions 88; substantially as set forth.

812,241. **COMB.** CHARLES M. SHUBERT, Philadelphia, Pa. Filed June 7, 1905. Serial No. 264,120.



Claim.—1. A comb having a body portion, teeth extending from said body portion and arranged in a curve with respect to the same, the ends of said teeth being arranged in a curve with respect to the longitudinal axis of the teeth so as to permit of a simultaneous engagement of all the teeth with the scalp of a head, when the comb assumes a certain oblique position with respect thereto.

2. A comb having a body portion, teeth having a chamber extending from said body portion and arranged in a curve with respect to the same, outlet-openings arranged above the closed ends of said teeth and adapted to connect the chamber thereof with the exterior surface of the same and the free ends of said teeth being arranged in a curve with respect to the longitudinal axis of the same.

3. A comb having a hollow body portion formed of yielding walls adapted to receive a liquid preparation, teeth having a chamber extending from said body portion and arranged in a curve with respect to the same and adapted to receive the liquid preparation from said body portion, outlet-openings arranged adjacent to the ends of said teeth and adapted to connect the chamber thereof with the exterior surface of the same and to conduct the liquid preparation thereto, the free ends of said teeth being arranged in a curve in respect to the longitudinal axis of the same, and the yielding walls of said body portion being adapted when moved toward each other to force the liquid preparation into the teeth and from the same over the free ends of the teeth.

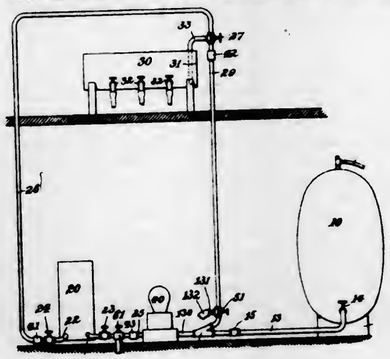
4. A comb having a hollow body portion, an air-valve having a projecting stem adapted, when depressed, to permit of the entrance of air into said body portion, hollow teeth extending from said body portion and arranged in a curve with respect to the same, openings arranged in each of said teeth adjacent to the closed end of the same and adapted to connect the interior of the teeth with the exterior surface thereof, said body portion and teeth adapted to receive a liquid preparation and to permit of an outflow of the same through said openings, and the free ends of said teeth arranged in a curve in respect to the longitudinal axis to permit in conjunction with the curvature in the location of the same with respect to the body portion of a simultaneous engagement of all the teeth with the scalp of the head.

5. A comb having a hollow body portion, an air-valve having a projecting stem adapted when depressed to permit of the entrance of air into said body portion, a screw-cap arranged in said body portion and adapted when removed therefrom to permit of the entrance of a liquid preparation into said body portion, hollow teeth extending from said body portion and arranged in a curve with respect to the same, openings arranged in each of said teeth adjacent to the closed end and adapted to connect the interior of the teeth with the exterior surface thereof, said body portion adapted to conduct the liquid into said teeth and to permit of an outflow through said openings and the free ends of said teeth arranged in a curve with respect to the longitudinal axis to permit in conjunction with the curvature in the location of the teeth with respect to said body portion of a simultaneous engagement of all the teeth with the scalp of the head.

812,242. **SHADE-FIXTURE.** SIDNEY L. SKINNER, Ottawa, Ill., assignor to Michael C. Seiter, Ottawa, Ill. Filed Mar. 7, 1905. Serial No. 248,840.

Claim.—A shade-fixture comprising bars, of rectangular form in cross-section, arranged horizontally with their inner portions lapped and having their outer ends bent forwardly to form brackets, a clamp having a body of rectangular form arranged on and supported by the lapped portions of the bars and also having a screw-bearing in the longitudinal center of one of its end walls and engaging the adjacent edges of the bars, and hangers having lateral arms at their upper ends terminating in depending barbs and also having eyes at their lower ends; the said eyes being rectangular in form and disposed parallel to the depending barbs so as to receive the horizontal bars and hold the latter against axial movement.

812,243. **CIRCULATING SYSTEM FOR BEER-FILTERS.** MAX STAHL, Chicago, Ill., assignor to Charles H. Loew, Lakewood, Ohio. Filed Mar. 18, 1905. Renewed Dec. 21, 1905. Serial No. 292,739.



Claim.—1. The combination with a beer-filter, a source of beer-supply under pressure and a suitable conduit leading therefrom to the filter, of means intermediate the source of supply and the filter whereby the column of fluid is kept supplied to the filter when the source of supply is cut off.

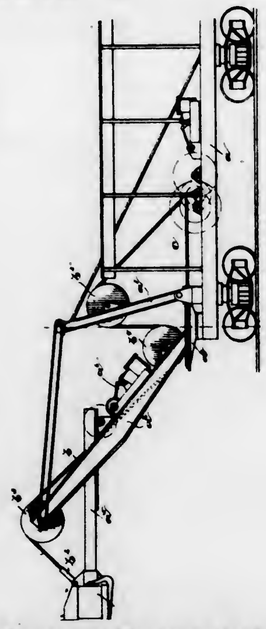
2. The combination with a beer-filter, a source of beer-supply under pressure and a suitable conduit leading therefrom to the filter, of means intermediate the source of supply and the filter whereby the column of fluid is kept supplied to the beer-filter when the source of supply is cut off, comprising a pump and connections between the same and the outlet and inlet of the filter.

3. The combination of a chip cask, a beer-filter and a racking apparatus with a pump a conduit leading thereto from the racking apparatus and a connection between the pump and the filter.

4. The combination of a chip cask, a beer-filter, a conduit between them, a pump a conduit from the outlet of the filter to the inlet of the pump means for connecting the outlet of the pump to the conduit leading from the chip cask to the filter and means forshutting off the beer from the chip cask.

5. The combination of a chip cask, a beer-filter, a racking apparatus and conduits between the chip cask and the filter and the racking apparatus and the filter, with a conduit leading from the racking apparatus to the filter, a pump in the line of said conduit and suitable valves whereby the supply of beer is cut off from the chip cask and the racking apparatus and caused to pass through the pump in a circulating current.

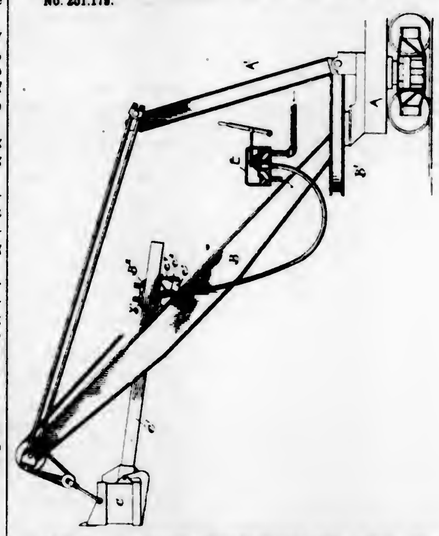
812,244. STEAM SHOVEL AND DREDGE. GEORGE B. TURNER, Bellefontaine, Ohio, assignor to The Bellefontaine Foundry & Machine Company, Bellefontaine, Ohio, a Corporation of Ohio. Filed Feb. 27, 1905. Serial No. 247,494.



Claim.—1. In a structure of the character described, a main portion, a swinging boom, a dipper, a housing adjacent thereto, a sheave withia said housing, a single-lead double hoisting-cable, the bight of which engages said sheave and operating means for said hoisting-cable, substantially as and for the purpose specified.

2. In a structure as described, a main portion, a swinging boom, and a superstructure thereon, double-grooved sheaves arranged in said boom and superstructure, a dipper, a housing adjacent thereto, a single-groove sheave withia said housing, a double hoisting-cable, the bight of which engages with said single-groove sheave, and which is led over the said double-grooved sheaves, and having a portion of its lead substantially coincident with the axial line of the swinging boom, substantially as and for the purpose specified.

812,245. STEAM-DREDGE. GEORGE B. TURNER, Bellefontaine, Ohio, assignor to The Bellefontaine Foundry & Machine Company, Bellefontaine, Ohio, a Corporation of Ohio. Filed Mar. 20, 1905. Serial No. 251,179.



Claim.—1. In a dredge, the combination with a dipper, and a handle therefor having straight parallel edges, of a grip for said dipper-handle comprising a shaft having bearings in the boom, bearing members on said shaft on which said dipper-handle rests, a plate above said dipper-handle, and coöperating with said bearing members to clamp said dipper-handle, and means for moving said plate in relation to said bearing-blocks, substantially as specified.

2. In a dredge, the combination with a dipper, and a handle therefor, of a grip for said dipper-handle comprising a shaft, a main-frame member on said shaft, bearing members on said shaft, longitudinally-movable members extending through said main-frame member, a plate secured to said longitudinally-movable members and adapted to engage the upper side of the dipper-handle, a yoke connecting said longitudinally-movable members, and an operating-lever adapted to move said longitudinally-movable members to cause the dipper-handle to be clamped between the said bearing members and plate, substantially as specified.

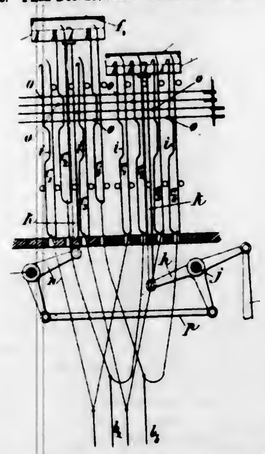
3. In a dredge, the combination with a dipper, and a handle therefor, of a grip for said dipper-handle comprising a shaft having bearings in the boom, a main-frame member secured to said shaft, bearing members also on said shaft, longitudinally-movable members located in said main-frame member, a plate secured to said longitudinally-movable members and adapted to operate with the bearing members to clamp the dipper-handle; a yoke connecting the lower extremities of said longitudinally-movable members, an operating member engaging with said yoke, a cylinder secured to said main-frame member and having a piston within said cylinder, a connection between the piston-rod of said piston and the operating-lever, whereby the dipper-handle will be clamped by said plate and bearing members by the operation of the piston within the cylinder, substantially as and for the purpose specified.

4. In a dredge, the combination with a dipper, and a handle therefor, of a grip for said handle, comprising a shaft having bearings in the boom, a main-frame member mounted on said shaft, longitudinally-movable members extending through said main-frame member, a plate secured to said longitudinally-movable members, and adapted to engage the upper side of the dipper-handle, bearing members supported on said shaft adapted to engage the lower side of the dipper-handle, a yoke connecting the lower extremities of said longitudinally-movable members, pendent links on said shaft forming a fulcrum for an operating-lever adapted to engage said yoke, a cylinder having a piston therein secured to the main-frame member, a connection between said piston and the operating-lever, substantially as and for the purpose specified.

5. In a dredge, the combination with a dipper and a handle therefor, a support, a stationary clutch member supported thereby, bearing members formed on said support on which said dipper-handle rests, a movable clutch member above said dipper-handle coöperating with said stationary clutch member to clamp said dipper-handle, an oscillating member, connections between said oscillating member and said movable clutch member, substantially as specified.

6. In a dredge, the combination with a dipper and a handle therefor, a support having bearings in the boom, a stationary clutch member formed on said support, a longitudinally-movable member, a movable clutch member secured to said longitudinally-movable member, an oscillating sleeve, a yoke connected to said sleeve, and also connected to said longitudinally-movable member, and connections between said piston and said oscillating sleeve, for the purpose specified.

812,246. JACQUARD-MACHINE FOR LOOMS. JULES VERDOL, Lyon, France. Filed Dec. 29, 1903. Serial No. 187,084.



Claim.—1. In a double-lifting jacquard-machine of the Verdol system, the combination of two griff-frames, provided with depressing-plates f', g' to cause the lifting-wires to descend, a cylinder-driver and a mechanism for drawing along the perforated paper moved alternately by the griff-frames, said mechanism consisting of a latch l acting upon the cylinder-driver at reduced speed so as to cause it to advance each time by one division, of a brake z preventing the cylinder-driver from being drawn along too far by its acquired speed, of a pulley-jack s, a large lever x actuating said pulley-jack at slight speed so as to bring finally the cylinder-driver into its position and to maintain it there.

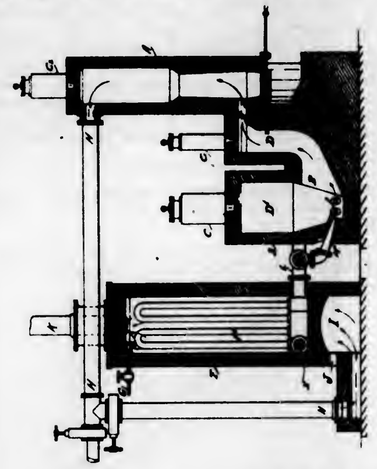
2. In a double-lifting jacquard-machine of the Verdol system, the combination of the two griff-frames, provided with depressing-plates, of a set of needles, lifting-wires, two of which are actuated by each needle, and of lifting-wires hollowed on one portion of their height so as to prevent them from being pushed back by the needles when they are lifted.

812,247. PROCESS OF REDUCING IRON ORE. GUSTAV M. WESTMAN, New York, N. Y. Filed June 24, 1903. Serial No. 163,576.

Claim.—1. The process of reducing iron ore which consists in subjecting air mixed with steam in a continuous heated current to the action of glowing coke to form carbon monoxid and hydrogen and so regulating the proportion of air to the steam that the resulting gases will have a temperature of about 1,100° centigrade and finally passing the gases at said temperature through the ores to be reduced, substantially as described.

2. The process of reducing iron ore which consists in subjecting air mixed with steam in a continuous heated current to the action of glowing coke having limestone mixed therewith, whereby carbon monoxid and hydrogen free from sulfur are formed and so regulating the proportion of air to the steam that the resulting gases will have a temperature of about 1,100° centigrade, and finally passing the gases at said temperature through the ores to be reduced, substantially as described.

3. The process of reducing iron ore which consists in introducing water into a continuous current of air, heating the mixed air and water to form steam, passing the air and steam through glowing coke to form carbon monoxid and hydrogen, regulating the proportion of air to the steam so that the resulting gases will have a temperature of about 1,100° centigrade and passing the gases at said temperature through the ores to be reduced, substantially as described.



4. The process of reducing iron ore which consists in introducing water into a continuous current of air, heating the mixed air and water to form steam, passing the air and steam through glowing coke mixed with limestone to form carbon monoxid and hydrogen free from sulfur, regulating the proportion of air to the steam so that the resulting gases will have a temperature of about 1,100° centigrade and passing gases at said temperature through the ores to be reduced, substantially as described.

5. The process of reducing iron ore which consists in subjecting air mixed with steam in a continuous heated current to the action of glowing coke to form carbon monoxid and hydrogen and so regulating the proportion of air to the steam that the resulting gases will have a temperature of about 1,100° centigrade and finally causing the gases at said temperature to act upon the ores to be reduced in the presence of a small percentage of carbon, substantially as described.

6. The process of reducing iron ore which consists in subjecting air mixed with steam in a continuous heated current to the action of glowing coke mixed with limestone to form carbon monoxid and hydrogen free from sulfur and so regulating the proportion of air to the steam that the resulting gases will have a temperature of about 1,100° centigrade and finally causing the gases at said temperature to act upon the ores to be reduced in the presence of a small percentage of carbon, substantially as described.

7. The process of reducing iron ore which consists in introducing water into a continuous current of air, heating the mixed air and water to form steam, passing the air and steam through glowing coke to form carbon monoxid and hydrogen, regulating the proportion of air to the steam so that the resulting gases will have a temperature of about 1,100° centigrade and finally causing the gases at said temperature to act upon the ores to be reduced in the presence of a small percentage of carbon, substantially as described.

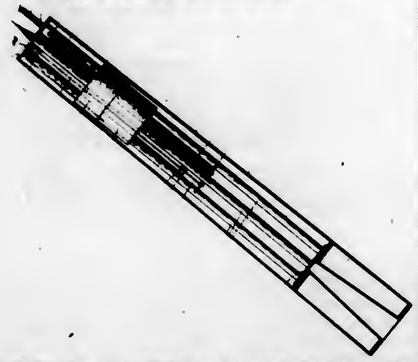
8. The process of reducing iron ore which consists in introducing water into a continuous current of air, heating the mixed air and water to form steam, passing the air and steam through glowing coke mixed with limestone to form carbon monoxid and hydrogen free from sulfur, regulating the proportion of air to the steam so that the resulting gases will have a temperature of about 1,100° centigrade and finally causing the gases at said temperature to act upon the ores to be reduced in the presence of a small percentage of carbon, substantially as described.

9. The process of reducing iron ore which consists in spraying water into a current of air, raising the temperature of the mixed air and water to form air and steam, passing the air and steam through incandescent carbon to form carbon monoxid and hydrogen, and subjecting the gases thus formed to the action of the incandescentt carbon, regulating the proportion of air to steam so that the resulting gases will have a temperature of about 1,100° centigrade, and then

causing the gases at said temperature to act upon the ores to be reduced in the presence of a small percentage of carbon, substantially as described.

10. The process of reducing iron ore which consists in spraying water into a current of air, raising the temperature of the mixed air and water to form air and steam, passing the air and steam through incandescent carbon mixed with lime to form carbon monoxid and hydrogen, and subjecting the gases thus formed to the action of the incandescent carbon and lime whereby pure gases are generated, regulating the proportions of the air and steam so that the resulting gases will have a temperature of about 1,100° centigrade, and then causing the gases at said temperature to act upon the ores to be reduced in the presence of a small percentage of carbon, substantially as described.

812,248. CANDLE-HOLDER. LEWIS M. WILDS, North Walpole, N. H. Filed Oct. 26, 1905. Serial No. 284,416.



Claim.—1. In a candle-holder, a counterweighted vertically-movable candle-receptacle, and means to vary the effective weight of the counterweight as the candle burns.

2. In a candle-holder, a vertically-movable candle-receptacle, a counterweight connected to the receptacle, and means to relieve the receptacle of a portion of the weight of the counterweight as said receptacle moves upwardly due to the burning of the candle.

3. In a candle-holder, a counterweighted vertically-movable candle-receptacle, means to engage the lighted end of the candle to maintain the flame in a constant position, and means to vary the effective weight of the counterweight as the candle burns.

4. In a candle-holder, a vertically-movable candle-receptacle, means to engage the lighted end of the candle thereby to maintain the flame in a constant position, a counterweight connected to the receptacle, and means to relieve the receptacle of a portion of the weight of the counterweight as said receptacle moves upwardly.

5. In a candle-holder, a vertically-movable candle-receptacle, a counterweight connected thereto, means to guide the candle-receptacle in its movement, and means to relieve it of a portion of the weight of the counterweight as the candle burns.

6. In a candle-holder, a vertically-movable candle-receptacle, a counterweight connected thereto, said counterweight being made in two parts, and means to arrest the movement of one part of the counterweight when the candle is partly burned.

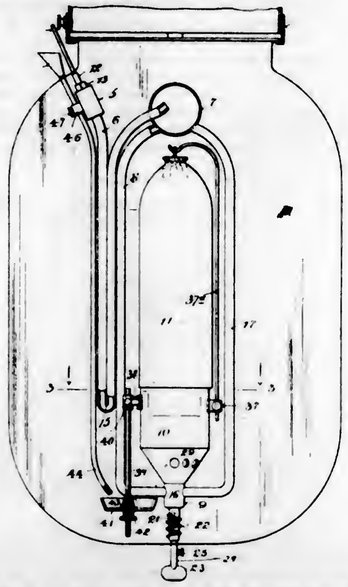
7. In a candle-holder, a vertically-movable candle-receptacle, a counterweight connected to said receptacle, said counterweight being made in two parts, a stop to engage one part as the counterweight descends and thereby relieve the candle-receptacle of a portion of the weight of the counterweight.

8. In a candle-holder, a vertically-movable candle-receptacle, guide-rods between which the receptacle moves and by which it is guided, a counterweight encircling the guide-bars and connected to the receptacle, said counterweight being made in two parts, and means to arrest the movement of one of the parts when the candle is partially burned.

9. In a candle-holder, a vertically-movable candle-receptacle, a counterweight therefor, and pivoted dogs to engage the lighted end of the candle.

10. In a candle-holder, a vertically-movable candle-receptacle, guide-rods between which said receptacle moves and by which it is guided, a guideway for the receptacle, and dogs pivoted to the guides and adapted to engage the upper end of the candle.

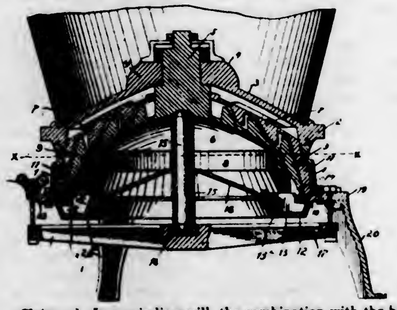
812,249. KEROSENE-LAMP. JACOB WILENTZ, New York, N. Y. Filed May 2, 1905. Serial No. 258,489.



Claim.—1. In an article of the class described a burner comprising a flared portion having perforations in one side only and covered by a centrally-perforated diaphragm, a tube extending about said central perforation, a cap having a serrated lower edge covering said tube, and a cylinder surmounting said flared portion and surrounding said cap.

2. In an article of the class described, a burner comprising a flared lower portion, a cylindrical tube surmounting said flaring portion; a gauze surmounting said tube, a perforated plate fixed to said flared portion at its top; a tube fixed to said plate and inclosing said opening, and a cap with serrations in its lower edges, inclosing said last-mentioned tube.

812,250. GRINDING-MILL. JAMES S. WOODCOCK, New Lexington, Ohio. Filed July 13, 1905. Serial No. 269,457.



Claim.—1. In a grinding-mill, the combination with the base-ring, its supports, the bridge-tree and the spindle, of means fixedly supported at each end by the base-ring and engaging with the spindle for holding the same in place.

2. In a grinding-mill, a base-ring having a trough formed therein provided with leg-engaging lugs, and legs secured to the lugs, and a detachable outer casing secured to the base-ring independently of the lugs and the legs.

3. In a grinding-mill, a base-ring formed with a trough provided with laterally-projecting lugs, and a bridge-tree supported from the lugs and having adjustable connection with one of said lugs.

4. In a grinding-mill, the combination with a base-ring formed with a trough, supports for the ring and a spindle supported within the ring, of bracing means for the spindle engaging about the same and extending across the base-ring.

5. In a grinding-mill, the combination with a base-ring formed with a trough, a conveyer mounted in the trough and a spindle supported within the ring, of a grinding member rotatably mounted on the upper end of the spindle and provided with a projecting flange, and an inner annular bar member fitting about the grinding member and resting on the flange thereof and provided with projections adapted to engage the conveyer to impart motion thereto.

6. In a grinding-mill, a base-ring having laterally-extending lugs, an outer casing detachably supported on the upper side of the base-ring and independently of the lugs, and legs detachably secured to the lugs independently of the casing, in combination with a spindle supported within the base-ring, and a grinding-cone supported on the upper end of the spindle.

812,251. LEVEL. TONY ALEXANDER, Brookhaven, Miss. Filed Mar. 25, 1905. Serial No. 252,076.

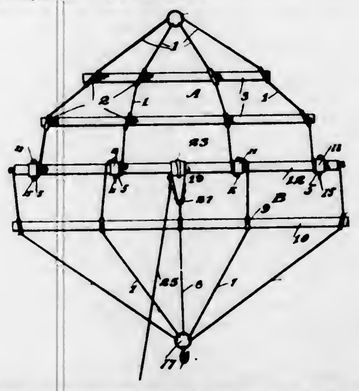
Claim.—1. In a leveling device, a hollow body of globular or spherical form filled with a liquid with the exception of a minute space forming an air-bubble, and having indicia at different points in its surface, each indice consisting of a series of concentric circles.

2. In a leveling device, a hollow body of globular or spherical form filled with a liquid with the exception of a minute space forming an air-bubble, and having indicia at different points in its surface, each indice consisting of a series of concentric circles, and a cross intersecting the lines of the circles and the centers of the cross and circles coinciding.

3. In a leveling device, a hollow body of spherical or globular form containing a liquid and an air-bubble, and provided with indicia at different points in its surface and formed with a neck and a base, said base being hollow upon its under side and the neck adapted to receive a stopper, the end of which is adapted to project into the space of said hollow base.

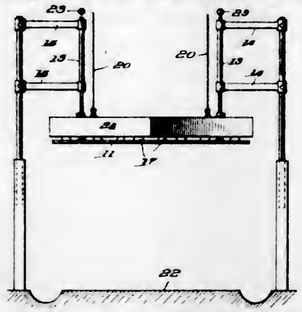
4. In a leveling device, a hollow body of globular form having indicia pressed into its inner surface to increase the concavity and containing liquid and an air-bubble.

812,252. HAY-NET. MORRIS H. ALLWARDT, Jordan Valley, Oreg. Filed Aug. 2, 1905. Serial No. 272,428.



Claim.—A hay-net comprising the complemental net parts A and B, each of said parts consisting of a plurality of transverse bars and a plurality of ropes connected therewith, one of the transverse bars of the part B being rotatable, pins projecting from the outer ends of the rotatable bars aforesaid and having the outermost ropes of the part B connected therewith, a supporting-arm projecting laterally from the central portion of the rotatable bar and provided with a bearing in which said bar is rotatably mounted, a clutch-flange projecting from the rotatable bar adjacent the bearing of the arm aforesaid and formed with a lateral cam extension, a locking-dog of bell-crank form pivoted to the arm, one arm of said dog being adapted to engage with the cam of the clutch-flange, the other arm of said dog having a pull-rope connected therewith, pins permanently applied to the rotatable bar adjacent its ends and having the extremities thereof detachably connected with the outermost ropes of the part A of the net, other pins detachably applied to the rotatable bar and having detachable connection at one end with the innermost ropes of the part A, the opposite ends of said detachable pins being permanently connected with ropes of the part B, rings connected with the outer ends of the several ropes of the parts A and B of the net, and a hook-pulley applied to one of the rings for the purpose specified.

812,253. BOWLING-ALLEY-PIN SPOTTER. CHARLES L. BASTIAN, Chicago, Ill. Filed Dec. 27, 1904. Serial No. 238,517.



Claim.—1. In a vertically-movable pin-spotter for bowling-alleys, normally open movable positioning devices, and means forming part of the movable spotter and normally out of operative engagement with said devices and movable relatively thereto for engaging and moving said devices into closed position to receive the pins.

2. A vertically-movable pin-spotter for bowling-alleys, comprising movable positioning devices constructed to open by gravity when the spotter is raised, and means forming part of the movable spotter for closing said devices to receive the pins, said devices and means being normally out of operative engagement and said means being adapted to engage and move the devices into closed position when the spotter is lowered to receive the pins.

3. A vertically-movable pin-spotter for bowling-alleys, embodying movable positioning devices, and means forming part of the movable spotter and located beneath said devices and normally out of operative engagement therewith for moving them into closed position to receive the pins.

4. A vertically-movable pin-spotter for bowling-alleys, comprising movable positioning devices, and a plate beneath said devices and movable relatively thereto for moving them into closed position to receive the pins.

5. In a vertically-movable pin-spotter for bowling-alleys, normally open pivoted positioning devices, and means forming part of the movable spotter and normally out of operative engagement with said devices and movable relatively thereto for engaging and swinging said devices into closed position to receive the pins.

6. A vertically-movable pin-spotter for bowling-alleys, embodying pivoted positioning devices, and means beneath said devices and normally out of operative engagement therewith and movable relatively thereto for engaging and swinging them into closed position to receive the pins.

7. A vertically-movable pin-spotter for bowling-alleys, comprising pivoted positioning devices, and a plate beneath said devices and movable relatively thereto for moving them into closed position to receive the pins.

8. A vertically-movable pin-spotter for bowling-alleys, embodying movable positioning devices, means for supporting said devices, and means normally out of operative engagement with said positioning devices and movable relatively thereto and adapted to engage and roove said devices into closed position.

9. A vertically-movable pin-spotter for bowling-alleys, embody-

ing movable positioning devices, means for supporting said devices, and a plate beneath the positioning devices and movable relatively thereto, said devices and plate being arranged to engage each other when the spotter is lowered to move the devices into closed position to receive the pins.

10. A vertically-movable pin-spotter for bowling-alleys, comprising a bottom plate, a top plate, one of said plates being movable relative to the other, and movable positioning devices suspended from the top plate and adapted to engage the bottom plate and be moved thereby into closed position to receive the pins.

11. In a vertically-movable pin-spotter for bowling-alleys, the combination of a bottom plate, a top plate, a fixed stop for limiting the downward movement of the bottom plate, and movable positioning devices carried by the top plate and adapted to engage the bottom plate and be moved thereby into closed position to receive the pins.

12. In a vertically-movable pin-spotter for bowling-alleys, the combination of two plates spaced apart one above the other and provided with openings to receive the pins, one of said plates being movable relative to the other, and normally open movable positioning devices arranged between said plates and adapted to be moved to closed position during the continued downward movement of said relatively movable plate by engagement with the other plate after it has come to rest.

13. In a vertically-movable pin-spotter for bowling-alleys, the combination of two members spaced apart one above the other, and movable toward and from each other and provided with openings to receive the pins, normally open movable positioning devices suspended from the under side of the top member and adapted to engage the bottom member, and a fixed stop for limiting the downward movement of the bottom member.

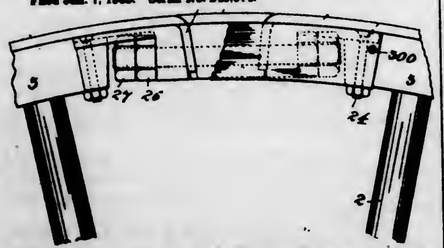
14. In a vertically-movable pin-spotter for bowling-alleys, the combination of two members spaced apart one above the other and movable toward and from each other and provided with openings to receive the pins, normally open movable positioning devices suspended from the under side of the top member, and guides on the bottom member arranged to be engaged by the positioning devices when said members move toward each other.

15. In a vertically-movable pin-spotter for bowling-alleys, the combination of two members spaced apart one above the other and movable toward and from each other and provided with openings to receive the pins, normally open movable positioning devices suspended from the under side of the top member and adapted to engage the bottom member, guides on the bottom member beneath the positioning devices, and a fixed stop for limiting the downward movement of the bottom member.

16. In a pin-spotter for bowling-alleys, the combination of a vertically-movable plate, rods connected to said plate and guided at the sides of the alley, devices for adjusting the downward movement of said plate, and movable positioning devices supported above said plate and movable vertically with and adapted to engage said plate.

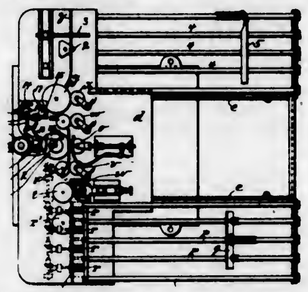
17. A vertically-movable pin-spotter for bowling-alleys, comprising movable positioning devices constructed to open by gravity when the spotter is raised, means for raising the spotter to clear the pins, and a single means forming part of the movable spotter and normally out of engagement with said positioning devices for simultaneously engaging and moving all of said devices into closed position to receive the pins when the spotter is lowered.

812,254. **TIRE-TIGHTENER.** LEWIS W. BENSON, Wichita, Kans. Filed Jan. 7, 1905. Serial No. 240,074.



Claim.—The combination with the abutting ends of a wheel or felly and a tire having downturned apertured ends, of an apertured bridge block or key inserted between said downturned ends, L-shaped supporting-blocks engaging the inner faces of said downturned ends, clips upon the ends of said rim or felly, a double screw passed through said blocks and the ends of said tire and having its center secured against rotation in said bridge-block, nuts upon the ends of said screw, a casing covering the inner and side faces of the ends of said rim or felly, and bolts or similar fastening means passed through the supporting-blocks, the felly, the clips and said casing, substantially as described.

812,255. **INKING APPARATUS FOR STAMP-CANCELING AND POSTMARKING MACHINES.** FREDRIK BJURSTRÖM, New York, N. Y. Original application filed July 8, 1904. Serial No. 215,534. Divided and this application filed Jan. 19, 1905. Serial No. 241,727.

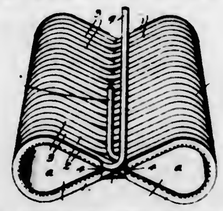


Claim.—1. The combination with the die-roll, and distributing-roll, of an ink-fountain having a lateral wick containing discharge-passage partitioned from the main space, the wick in the main space connecting with the wick of the discharge-passage over the partition, and a clamp gripping the wick on the top of the partition.

2. The combination with the die-roll, and distributing-roll, of an ink-fountain having a lateral wick containing discharge-passage partitioned from the main space, the wick in the main space connecting with the wick of the discharge-passage over the partition, vertical guard-flanges to the wick-passage, and a clamp gripping the wick on the top of the partition.

3. The combination with the distributing-roll, of a pivoted support therefor, a lever-arm of said support, a notched keeper-latch engaging said lever-arm, and a spring to maintain the engagement.

812,256. **APPARATUS FOR COOLING LIQUIDS.** GEORGE F. BLACK, Baltimore, Md. Filed July 31, 1905. Serial No. 272,087.



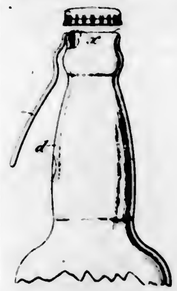
Claim.—1. A liquid-cooling apparatus comprising tubular core-pieces, a pipe having inner coils extending around the core-pieces and crossed between said core-pieces, and outer coils also extending around the core-pieces and disposed intermediate the inner coils.

2. A liquid-cooling apparatus comprising tubular core-pieces having outwardly-extending flanges at their ends, a pipe having inner coils extending around the core-pieces and crossed between said core-pieces, and outer coils also extending around the core-pieces and disposed intermediate the inner coils, and having their intermediate portions opposite the crossed portions of the inner coils spaced therefrom.

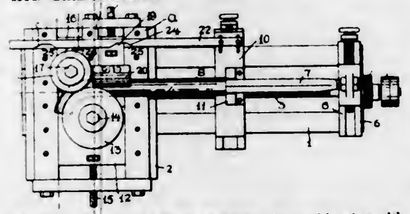
812,257. **BOTTLE-CAP LIFTER.** ALBA C. BOOTH, Burlington, Vt. Filed Feb. 1, 1905. Serial No. 243,671.

Claim.—A bottle provided with a groove or slot on one side into which a lifter may be inserted for removing the cap from the bottle, the said groove terminating in a notch at its upper end as herein described.

812,257.



812,258. **AUTOMATIC BENDING-MACHINE.** LOUIS H. BRINKMAN, West Hartford, Conn., assignor to Whitlock Coil Pipe Company, West Hartford, Conn., a Corporation of Connecticut. Filed Dec. 12, 1904. Serial No. 236,515.



Claim.—1. In a pipe-bending machine, the combination with a forming-roll and a bending-roll, of means for advancing a pipe between said rolls, and means automatically controlled by the movement of the pipe for moving the bending-roll toward said forming-roll.

2. In a pipe-bending machine, the combination with a forming-roll and a bending-roll, of means for advancing a pipe between said rolls, and means for advancing said bending-roll toward said forming-roll, and for allowing it to recede therefrom at predetermined points in the movement of the pipe.

3. In a pipe-bending machine, the combination with a forming-roll, of a bending-roll, means for advancing a pipe to be bent between said rolls, and a recessed plate for advancing said bending-roll to an operative position and allowing it to withdraw therefrom, means for longitudinally moving said plate simultaneously with the movement of the pipe.

4. In a pipe-bending machine, the combination with a forming-roll and a bending-roll, of means for advancing a pipe to be bent between said rolls, and means automatically controlled by the movement of the pipe for advancing said bending-roll toward said forming-roll, for holding it in said position and for allowing it to recede therefrom.

5. In a pipe-bending machine, the combination of forming and bending rolls, a fixed mandrel, means for imparting a longitudinal movement to the pipe on said mandrel and between said rolls, and means automatically controlled by the movement of the pipe for moving the bending-roll toward said forming-roll.

6. In a pipe-bending machine, the combination of a mandrel held at one end from longitudinal movement, with its free end adapted to enter the pipe to be bent, means for pushing the pipe off the free end of the mandrel, a forming and a bending roll arranged to apply a bending strain to the pipe as it is delivered from the mandrel, means for adjusting said rolls relatively to the mandrel, and means for moving the bending-roll relatively to the forming-roll as determined by the longitudinal movement of the pipe.

7. In a pipe-bending machine, the combination of a framework provided with ways, a carriage movable along said ways, means for actuating said carriage, a mandrel held at one end from longitudinal movement, a pusher-plate attached to said carriage and adapted to contact with the end of a pipe held on said mandrel, a forming-roll, a bending-roll, arranged to apply a bending strain to the pipe as it is pushed from the free end of said mandrel, means for moving the bending-roll toward the forming-roll as determined by the forward movement of the pipe, and a support for the pipe behind said bending-roll and opposite the forming-roll.

8. In a pipe-bending machine, the combination of bending and forming rolls for applying a bending strain to a pipe passing between said rolls, a mandrel held at one end with its free end adapted to enter the pipe, means for forcing the pipe off the free end of the mandrel, and means automatically controlled by the movement of the pipe, for changing the position of said rolls relatively to each other.

9. In a pipe-bending machine, the combination of a forming-roll, a bending-roll, means for imparting a longitudinal movement to the pipe to be bent between said rolls, a slidable block carrying said bending-roll, and means for moving said slidable block consisting of a recessed plate and means for moving said plate simultaneously with the forward movement of the pipe.

812,259. **TIRE-PROTECTOR.** JOHN E. CAPS, Kansas City, Mo. Filed Jan. 31, 1905. Serial No. 243,477.

Claim.—1. In a tire-protector, a yielding body, and a puncture-resisting member located therein and comprising a strip of resilient material extending longitudinally through the body and disposed in a plurality of overlapping convolutions.

2. In a tire-protector, a yielding body having an outer shoe comprising sections, rivets connecting the sections and constituting anti-slipping devices, and a puncture-resisting member located inside the shoe and comprising a strip of resilient sheet metal extending longitudinally through the body in a plurality of overlapping convolutions.

3. In a tire-protector, a yielding body, a puncture-resisting member located in and covered by the body and consisting of a plurality of layers, binidngs embracing the edges of the layers, a lining located inside the member, and means for fastening the protector upon a tire.

4. In a tire-protector, a yielding body, a puncture-resisting member located in the body and constituting a plurality of layers, bindings embracing the edges of the layers, and fastening means for securing the member in the body, said means engaging the body and passing through the bindings.

5. In a tire-protector, a yielding body having an outer shoe, a puncture-resisting member located in the body inside the shoe and consisting of a plurality of layers, bindings embracing the edges of the layers, and fastening means for securing the member in the body, said means passing through the bindings and the shoe.

6. In a tire-protector, a yielding body having a shoe comprising sections, a puncture-resisting member comprising a resilient sheet-metal strip wound into a plurality of overlapping convolutions or layers, bindings embracing the margins of the layers, rivets passing through the sections of the shoe and projecting beyond the same to form antislipping means, and rivets passing through the binding and the shoe and projecting beyond the same, said latter rivets also constituting antislipping means.

7. In a tire-protector, a yielding body having a shoe, a metallic puncture-resisting member located inside the shoe, puncture-resisting scales interposed between the member and shoe, a lining located inside the puncture-resisting member, and means for securing the protector over a tire.

8. In a tire-protector, a yielding body having a shoe, a puncture-resisting member located inside the shoe, puncture-resisting scales interposed between the member and shoe, each of said scales extending transversely of said member and shoe and the width of the former, and means for securing the protector over a tire.

9. In a tire-protector, a yielding body having an outer shoe, a puncture-resisting member located inside the shoe, fastening devices for securing the shoe and member together, and scales interposed between the member and shoe and extending transversely thereof, said scales having their terminals located between the fastening devices.

10. In a tire-protector, a yielding body having an outer shoe, a

puncture-resisting member located inside the shoe and consisting of a plurality of layers of resilient sheet metal, bindings embracing the margins of the layers, spaced fastening devices extending through the bindings and the shoe, and scales interposed between the shoe and the member and having tapered terminals that engage between the fastening devices.

11. In a tire-protector, a yielding body having an outer shoe comprising sections of flexibe material, a metallic puncture-resisting member located inside the shoe, a lining arranged inside the member and fastening devices passing through the shoe and terminating at the metallic member, said devices projecting beyond the shoe to constitute antislipping means, and said metallic member preventing the wearing of the lining by the fastening devices.

12. In a tire-protector, a yielding body having an outer shoe comprising sections, a puncture-resisting member located inside the shoe and comprising superposed layers, bindings covering the margins of the layers, fastening devices passing through the shoe and terminating at the member, and other fastening devices for securing the member and shoe together and passing through the bindings, said devices projecting beyond the shoe to form antislipping means.

13. In a tire-protector, a yielding body having an outer shoe comprising longitudinally-disposed sections, a puncture-resisting member located inside the shoe and comprising a strip of sheet metal wound into a plurality of superposed convolutions, metal binding-stripe embracing the margins of the convolutions, a plurality of spaced fastening devices passing through the bindings and through the shoe, transversely-disposed scales interposed between the member and shoe and having their terminals located between said fastening devices, and other fastening devices for securing the shoe-sections together, said devices terminating at the scales and projecting beyond the shoe to constitute antislipping means.

14. In a tire-protector, the combination with a shoe, of means for securing the same upon a tire, a heat-insulating lining located inside the shoe, and puncture-resisting means interposed between the shoe and lining.

15. In a tire-protector, the combination with a shoe, of means for securing the same upon a tire, a metallic puncture-resisting member disposed inside the shoe and a heat-insulating lining located inside the member and having a yielding granular body, said lining being interposed between the member and tire when the protector is in place on said tire.

16. In a tire-protector, the combination with a shoe, an inner heat-insulating lining having a yielding body of granular cork, and an interposed puncture-resisting member comprising yielding metallic layers, of means for attaching the protector to a tire.

17. In a tire-protector, the combination with a shoe, of means for attaching the same upon an ordinary tire, and a heat-insulating lining located inside the shoe and comprising a casing of spaced walls, and a body of granular cork located between said walls.

18. In a tire-protector, the combination with a shoe, of a puncture-resisting member located inside the same, a heat-insulating lining disposed inside the member, means for connecting said several elements, and means for attaching the protector to a tire.

19. In a tire-protector, the combination with a shoe, of a resilient sheet-metal puncture-resisting member arranged inside the same and formed of a strip having overlapping convolutions, means for securing the shoe and member together, a casing located inside the member, a body of granular cork arranged in the casing, and means for securing the casing and shoe together.

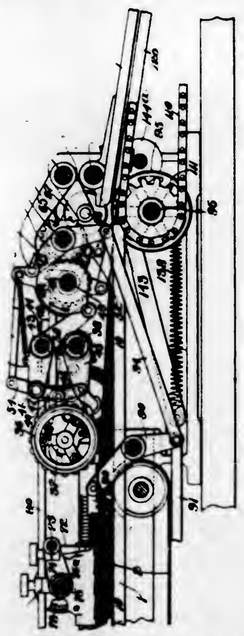
20. In a tire-protector, the combination with a yielding body having puncture-resisting means, of hinge-ears comprising doubled straps embracing the margins of the body and projecting therefrom, and other ears hinged to the projecting portions of said first-mentioned ears and carrying rim-engaging hooks.

21. In a tire-protector, the combination with a puncture-resisting metal strip, of a resilient coating of waterproof material covering the strip, and a body inclosing the strip and coating, and including an outer shoe, and means for attaching the protector to a tire.

22. In a tire-protector, the combination with a member comprising a plurality of puncture-resisting layers of thin metal, of resilient waterproof material covering said layers, a lining covering the inner side of the member, a shoe covering the outer side of said member, and means for securing the protector over a tire.

23. In a tire-protector, the combination with a body partially circular in cross-section, of a plurality of puncture-resisting layers formed of thin sheet metal, and layers of resilient waterproof material interposed between the puncture-receiving layers, the whole being inclosed by said body, and means for securing the said protector upon a tire.

812,260. **SHEET-FEEDING MACHINE.** FRANK L. CROSS, Mystic, Conn., assignor to Cross Paper Feeder Company, Boston, Mass., a Corporation of Maine. Filed July 12, 1902. Serial No. 115,308.



Claim.—1. In a sheet-feeder the combination with a support, of a movable loader, provided with means for laying a bank of feathered sheets upon said support as it moves over said support, substantially as described.

2. In a sheet-feeder the combination with a support, of a loader, means for operating said loader to lay a bank of feathered sheets upon said support, and means for feeding forward said bank and loader, substantially as described.

3. In a sheet-feeder the combination with sheet-separating devices, of a feed-table, a loader, means for operating said loader to lay a bank of feathered sheets upon said feed-table, and means for feeding said bank and loader toward the separating devices, substantially as described.

4. In a sheet-feeder the combination with a feed-table, of a movable loader comprising a supply-table, a curved guideway leading from the supply-table to the feed-table and means for feeding a bank of feathered sheets through the curved throat as the loader moves over the feed-table, substantially as described.

5. In a sheet-feeder the combination with a feed-table, of a movable loader comprising a supply-table, a feed-drum between the end of the supply-table and feed-table, curved guides coöperating with said feed-drum to form a curved guideway leading from the supply-table to the feed-table, and means for rotating said drum as the loader moves over the supply-table, substantially as described.

6. In a sheet-feeder the combination with a feed-table, of a loader comprising a supply-table, a curved guideway leading from said supply-table to said feed-table, a feeding-drum on one side of said curved guideway, a rack a gear connected with said drum and engaging said rack whereby as the loader is moved the drum is rotated, substantially as described.

7. In a sheet-feeder the combination with a feed-table, of a loader comprising a supply-table and feeding means for transferring a bank of feathered sheets from the supply-table to the feeding-table, a worm-wheel connected to said means, a screw-shaft engaged by said worm-wheel, whereby the operation of the feeding means is accompanied by a movement of the loader over the feed-table, and means for locking the worm-wheel whereby a rotation of the screw-shaft advances the loader without operating the feeding means, substantially as described.

8. In a sheet-feeder the combination with a feed-table, and means for advancing a feathered bank of sheets thereon, of a loader comprising a supply-table, a curved guideway leading from said supply-table to said feed-table, a feed-drum at one side of said guideway, worm-wheels connected with said drum, screw-shafts engaging said worm-wheels, means for locking said worm-wheels, whereby rotation of said shafts or rotation of said worm-wheels will move said loader, substantially as described.

9. In a sheet-feeder the combination with a feed-table of a loader comprising a supply-table, a drum between the tables, curved guides coöperating with said drum to form a curved guideway, pressure-rolls coöperating with said drum to feed a bank of feathered sheets through the guideway and means for rotating said drum and rolls and for moving the loader over the feed-table, substantially as described.

10. In a sheet-feeder the combination with feeding mechanism, of mechanism for arresting the action of the same, a latch for engaging said arresting mechanism and holding it out of operation, a pawl through the movement of which the latch is disengaged, and a toothed member for operating said pawl with which the pawl is engaged by the action of the sheet, substantially as described.

11. In a sheet-feeder the combination with a feeding device, of mechanism for arresting the action of the same, a latch for engaging said arresting mechanism and holding it out of operation, a pawl through the movement of which the latch is disengaged, a toothed member for operating said pawl with which the pawl is engaged by the action of the sheet, and mechanism for resetting the arresting mechanism, substantially as described.

12. In a sheet-feeder the combination with a combing-roll, of mechanism for lifting the same from the sheets, a latch for engaging said lifting mechanism and holding it out of action, a pawl connected with said latch, and a toothed member for operating said pawl to disengage said latch, and means for engaging said pawl with said toothed member by the action of the sheet, substantially as described.

13. In a sheet-feeder the combination with a combing-roll, of devices for lifting the same from the sheets, a lever connected with said devices, a latch for engaging said lever and preventing its movement, a pawl connected with said latch, a toothed member for operating said pawl to disengage said latch, means for engaging said pawl with said toothed member by the action of the sheet, and a cam for returning said lever into position to be engaged by said latch, substantially as described.

14. In a sheet-feeder the combination with a combing-roll, of an arm for engaging the sheets, a toggle connected with said arm and combing-roll, mechanism controlled by the sheet for straightening the toggle to bring the arm upon the sheets and lift the combing-roll, substantially as described.

15. In a sheet-feeder the combination with a combing-roll, of an arm for engaging the sheets, a shaft from which the combing-roll is supported, a toggle between said arm and shaft, and mechanism controlled by the sheet for straightening said toggle to bring the arm upon the sheets and lift the combing-roll, substantially as described.

16. In a sheet-feeder the combination with a combing-roll, of an arm for engaging the sheets, a shaft from which the combing-roll is supported, a toggle between said arm and shaft, mechanism controlled by the sheet for straightening the toggle to bring the arm upon the sheets and lift the combing-roll, and mechanism for thereafter lifting said arm from the sheets, substantially as described.

17. In a sheet-feeder the combination with a combing-roll, of an arm for engaging the sheets, a toggle connected with said arm and combing-roll, mechanism controlled by the sheet for straightening said toggle to bring the arm upon the sheets and lift the combing-roll, mechanism for raising and lowering the arm and combing-roll, and mechanism for contracting the toggle prior to the lowering of the combing-roll and arm, substantially as described.

18. In a sheet-feeder the combination with a combing-roll, of an arm for engaging the sheets, devices between the arm and roll for lifting the roll when the arm is depressed, sheet-controlled mechanism for operating said devices to bring the arm upon the sheets and lift the combing-roll, and mechanism for lifting said arm from the sheets, substantially as described.

19. In a sheet-feeder the combination with a combing-roll, of an arm for engaging the sheets, devices between the arm and roll for lifting the roll when the arm is depressed, sheet-controlled mechanism for operating said devices to bring the arm upon the sheets and lift the combing-roll, mechanism for raising and lowering the arm and combing-wheel, and mechanism for resetting the devices between the arm and roll prior to the lowering of the arm and roll, substantially as described.

20. In a sheet-feeder the combination with a combing-roll, of a clamp arranged to engage the top sheet and hold it in place and means for engaging said clamp with the top sheet when the combing-roll is thrown out of action, substantially as described.

21. In a sheet-feeder the combination with a combing-roll, of delivery devices, a clamp, means for engaging the clamp with the top sheet when the combing-roll is thrown out of action, and means for disengaging said clamp from the sheet when the delivery devices are thrown into action, substantially as described.

22. In a sheet-feeder the combination with a combing-roll, of delivery devices, a clamp, means for engaging said clamp with the top sheet when the combing-roll is thrown out of action and disengaging said clamp when the delivery devices are thrown into action, a second clamp and means for engaging said clamp with the second sheet prior to the action of the delivery devices and disengaging said clamp prior to the action of the combing-roll, substantially as described.

23. In a sheet-feeder the combination with sheet-separating devices of a clamp for engaging the sheets, mechanism for lowering said clamps upon banks of varying height and raising said clamp a substantially fixed distance above the top of the bank, substantially as described.

24. In a sheet-feeder the combination with a clamp, of a ratchet connected therewith, a reciprocating pawl for engaging said ratchet to raise and lower said clamp, and means for disengaging said pawl on lowering stroke, and engaging it on the raising stroke, whereby the clamp is raised the same distance above the sheets each time, substantially as described.

25. In a sheet-feeder the combination with sheet-separating devices, delivery devices to which the sheets are presented by the separating devices, guides in front of which the sheets are delivered by the delivery devices, and means for operating the delivery devices to start the sheets with an accelerated motion and to bring the sheet into position at the front guides with a retarded motion, substantially as described.

26. In a sheet-feeder the combination with combing-rolls the action of which is arrested by the top sheet, delivery devices to which the sheet is presented by the combing-rolls, and means for operating the delivery devices to grasp and release the sheet when both the sheet and delivery devices are at substantially a state of rest, substantially as described.

27. In a sheet-feeder the combination of a set of rolls to which the sheets are presented, a set of forwarding-rolls, guides for supporting the sheets advanced by said rolls, and means for intermittently engaging the rolls in each set with each other, and means for rotating said rolls when engaged with an accelerated and then a retarded speed, substantially as described.

28. In a sheet-feeder the combination of rolls 95, guides 120, rolls 103, a crank, connections between said crank and rolls 95 and 103 for rotating said rolls, drop-rolls 97 and 105 for coöperating with rolls 95 and 103, to advance the sheet, substantially as described.

29. In a sheet-feeder the combination with a combing device controlled by the sheet advanced thereby, of mechanism for feeding a bank of feathered sheets to said device, and means for operating said mechanism during the comb succeeding a long comb, substantially as described.

30. In a sheet-feeder the combination with a combing device controlled by the sheet advanced thereby, of mechanism for feeding a bank of feathered sheets to said device, and means for operating said mechanism to feed the bank during substantially the entire comb succeeding a long comb, substantially as described.

31. In a sheet-feeder the combination with a combing device controlled by the sheet advanced thereby, of mechanism for feeding a bank of feathered sheets to said device, and means for operating said mechanism to feed the bank of sheets when there is an increase in the length of comb, substantially as described.

32. In a sheet-feeder the combination with a combing device, controlled by the sheet advanced thereby, of mechanism for feeding a bank of feathered sheets to said device, and means for operating said mechanism when there is an increase in the comb to feed the bank a distance proportional to the increase, substantially as described.

33. In a sheet-feeder the combination with a combing device, of mechanism for feeding a bank of feathered sheets to said device, comprising a ratchet and a reciprocating pawl, and means dependent upon the advance of the sheet by the combing device for controlling the advancing action of said pawl, substantially as described.

34. In a sheet-feeder the combination with a combing device, of mechanism for feeding a bank of feathered sheets to said device, comprising a ratchet and a reciprocating pawl, and means dependent upon the advance of the sheet by the combing device for arresting the advancing action of said pawl, substantially as described.

35. In a sheet-feeder the combination with a combing device.

of mechanism for feeding a bank of feathered sheets to said device, comprising a ratchet and reciprocating pawl, and means dependent upon the advance of the sheet by the combing device for arresting the advance of said pawl, substantially as described.

36. In a sheet-feeder the combination with a combing device, of mechanism for feeding a bank of feathered sheets to said device comprising a ratchet, a pawl, means for advancing said pawl, means for returning said pawl to initial position, and sheet-controlled means for arresting said advancing means, substantially as described.

37. In a sheet-feeder the combination with a combing device, of mechanism for feeding a bank of feathered sheets to said device comprising a ratchet, a pawl, a pawl-carrying lever, a reciprocating rod for moving said lever in one direction, a spring for moving said lever in the other direction, a ratchet-bar connected with said lever, and a stop-pawl engaged with said bar by the action of the sheet, substantially as described.

38. In a sheet-feeder, the combination with a combing-roll, of mechanism for lowering said roll upon banks of varying thickness and raising said roll a substantially fixed distance above the top of the bank, substantially as described.

39. In a sheet-feeder, the combination with a combing-roll, of a ratchet connected therewith, a reciprocating pawl for engaging said ratchet to raise and lower said roll which disengages said ratchet on the lowering stroke, whereby the combing-roll is raised substantially the same distance above the sheets each time, substantially as described.

40. In a sheet-feeder the combination with a combing-roll, of a lever for raising and lowering the same, a ratchet-bar connected to said lever, a pawl-carrying lever, a pawl carried by said pawl-carrying lever, a stop for the pawl whereby the pawl disengages the ratchet-bar on the return stroke, and a cam for oscillating said pawl-carrying lever, substantially as described.

41. In a sheet-feeder the combination with sheet-separating devices, delivery devices provided with traveling surfaces for engaging and feeding forward the sheets to which the sheets are presented by the separating devices, guides in front of which the sheets are delivered by the delivery devices, and means for starting said traveling surfaces with an accelerated motion and stopping them with a retarded motion, substantially as described.

42. In a sheet-feeder the combination of sheet-separating devices, delivery devices provided with traveling surfaces acting progressively along the sheet to feed it forward, guides in front of which the sheets are delivered by the delivery devices, and means for moving said traveling surfaces from substantially a state of rest with an accelerated motion as the sheets are presented to them and with a retarded motion when they deliver the sheets at the front guides, substantially as described.

43. In a sheet-feeder the combination with sheet-separating devices, delivery devices provided with traveling surfaces acting progressively along the sheet to feed it forward, guides in front of which the sheets are delivered by the delivery devices, and means for moving said traveling surfaces with a gradually-retarded motion as they deliver the sheet at the front guides, substantially as described.

44. In a sheet-feeder the combination of delivery devices, provided with traveling surfaces acting progressively along the sheet to feed it forward, mechanism for presenting individual sheets to the delivery devices, means for operating said traveling surfaces to grasp and release the sheet when both the sheet and said surfaces are approximately at rest, and means for operating said traveling surfaces to start the sheet with an accelerated motion and to stop it with a gradually-retarded motion, substantially as described.

45. In a sheet-feeder the combination of delivery devices, provided with traveling surfaces acting progressively along the sheet to feed it forward, mechanism for presenting individual sheets to the delivery devices, and means for operating the traveling surfaces to start the sheet from substantially a state of rest with an accelerated motion and to bring it into position with a gradually-retarded motion, substantially as described.

46. In a sheet-feeder the combination of delivery-rolls, mechanism for presenting individual sheets thereto, and means for operating said rolls to advance the sheet from approximately a state of rest with an accelerated motion and to bring the sheet into position with a gradually-retarded motion, substantially as described.

47. In a sheet-feeder the combination of delivery devices provided with traveling surfaces acting progressively along the sheet to feed it forward, mechanism for presenting individual sheets to the delivery devices, and means for operating said traveling surfaces to grasp and release the sheets when both the sheet and the surfaces are approximately at rest, substantially as described.

48. In a sheet-feeder the combination of devices separating individual sheets, delivery devices to which the sheets are presented, provided with traveling surfaces acting progressively along the sheets to feed them forward, and means for operating the traveling surfaces to grasp and release the sheet when both the sheet and surfaces are approximately at rest, substantially as described.

49. In a sheet-feeder the combination of delivery-rolls, mechanism for presenting individual sheets thereto, and means for gradually retarding the motion of said rolls as they complete their forwarding action, substantially as described.

50. In a sheet-feeder the combination of delivery devices, provided with traveling surfaces acting progressively along the sheet to feed it forward, mechanism for presenting individual sheets to the delivery devices, means for operating said traveling surfaces to bring the sheet into position with a retarded motion and to release the sheet when the surfaces and sheets are approximately at rest, substantially as described.

51. In a sheet-feeder the combination of delivery devices, provided with traveling surfaces acting progressively along the sheet to feed it forward, mechanism for presenting individual sheets to said delivery devices, and means for operating said surfaces to grasp the sheet when the surfaces and sheet are approximately at rest and to start the sheet with an accelerated motion, substantially as described.

52. In a sheet-feeder the combination of delivery-rolls, mechanism for presenting individual sheets thereto, and means for operating said rolls to advance the sheet from a state of rest with an accelerated motion, substantially as described.

53. In a sheet-feeder the combination of delivery devices provided with traveling surfaces acting progressively along the sheet to feed it forward, mechanism for presenting individual sheets to said delivery devices, and means for gradually retarding the motion of said traveling surfaces as they complete their forwarding action, substantially as described.

54. In a sheet-feeder the combination of delivery devices provided with traveling surfaces acting progressively along the sheet to feed it forward, guides in front of which the sheets are delivered by the delivery devices, and means for gradually retarding said surfaces as they bring the sheets into position at the guides, substantially as described.

55. In a sheet-feeder the combination with a combing device, of mechanism for feeding a bank of feathered sheets to said device, comprising a ratchet and reciprocating pawl, and means for arresting the advancing action of said pawl when the combing ceases, substantially as described.

56. In a sheet-feeder the combination with combing-rolls the action of which is arrested by the top sheet, delivery-rolls between which the sheet is advanced by the combing-rolls, means for engaging and disengaging said rolls, a supplemental set of delivery-rolls, front guides, and means for gradually retarding the motion of said supplemental rolls to deliver the sheet at the front guides with a gradually-retarded motion, substantially as described.

57. In a sheet-feeder the combination of sheet-delivery devices provided with surfaces acting progressively along the sheet, mechanism for presenting individual sheets to the delivery devices, means for reciprocating said surfaces and varying their speed to deliver the sheets with a gradually-retarded motion, substantially as described.

58. In a sheet-feeder the combination of delivery-rolls, means for presenting individual sheets thereto, a second set of rolls, front guides and means for gradually retarding the motion of said second set of rolls as they forward the sheet to the front guides, substantially as described.

59. In a sheet-feeder the combination of two sets of delivery devices provided with surfaces acting progressively along the sheet, means for operating said devices to transfer the sheet from the first set of devices to the second when both sets are traveling at substantially the same surface speed, front guides before which the sheets are delivered by the second set of delivery devices, and means for gradually retarding the second set of devices as they deliver the sheet.

60. In a sheet-feeder the combination of delivery-rolls for forwarding sheets, supplemental delivery devices provided with surfaces acting progressively along the sheet, front guides before which the sheets are delivered by the supplemental devices, and means for giving the supplemental devices substantially the same surface speed as the rolls as the sheet is transferred to said devices and then retarding the surface speed of said supplemental devices to slow down the sheet.

61. In a sheet-feeder the combination with a combing-roll, of a sheet-retaining device and means for forcing said device against the top sheet with a retaining pressure when the combing-roll is thrown out of action, substantially as described.

62. In a sheet-feeder the combination with a combing-roll, of delivery devices, a sheet-retaining device, means for forcing said device against the top sheet with a retaining pressure when the combing-roll is thrown out of action, and means for relieving said pressure when the delivery devices are thrown into action.

63. In a sheet-feeder the combination with two independently-controlled sheet-advancing devices, a sheet-retaining device corresponding to each advancing device, means for forcing each retaining device against the top sheet with a retaining pressure when the corresponding advancing device is thrown out of action, substantially as described.

64. In a sheet-feeder the combination with two independently-controlled sheet-advancing devices, of sheet-delivery devices, a sheet-retaining device corresponding to each advancing device, means for forcing each retaining device against the top sheet with a retaining pressure when the corresponding advancing device is thrown out of action, and means for relieving the pressure of the retaining devices when the delivery devices are thrown into action, substantially as described.

65. In a sheet-feeder the combination with two independently-controlled combing-rolls, a sheet-retaining clamp corresponding to each roll, means for forcing each clamp against the top sheet with a retaining pressure when the corresponding combing-roll is thrown out of action, substantially as described.

66. In a sheet-feeder the combination with two independently-controlled combing-rolls, delivery devices, a sheet-retaining clamp corresponding to each roll, means for forcing each clamp against the top sheet with a retaining pressure when the corresponding combing-roll is thrown out of action, and means for relieving said pressure when the delivery devices are thrown into action, substantially as described.

67. In a sheet-feeder the combination with two independently-controlled combing-rolls, a sheet-retaining clamp corresponding to each roll, means for engaging each clamp with the top sheet when the corresponding combing-roll is thrown out of action, substantially as described.

68. In a sheet-feeder the combination with two independently-controlled combing-rolls, delivery devices, a sheet-retaining clamp corresponding to each roll, means for engaging each clamp with the top sheet when the corresponding combing-roll is thrown out of action, and means for disengaging said clamps when the delivery devices are thrown into action, substantially as described.

69. In a sheet-feeder the combination with a combing-roll, of a frame carrying said roll, mechanism for raising and lowering said frame at regular intervals, an arm for engaging the sheets, and sheet, controlled devices between said arm and frame for raising said frame and supporting it from the arm, substantially as described.

70. In a sheet-feeder the combination with a combing-roll, of a frame carrying said roll, an arm adapted to bear upon the sheets, sheet-controlled devices between the arm and frame for raising said frame and supporting it from the arm, delivery devices, and mechanism for raising the combing-roll frame when the delivery devices are thrown into action, substantially as described.

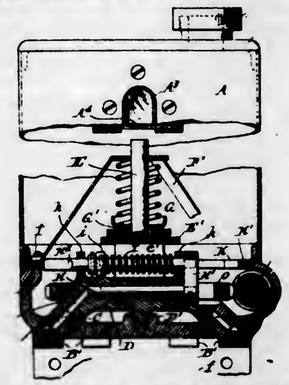
71. In a sheet-feeder the combination with a combing-roll, of a frame carrying said roll, an arm adapted to bear upon the sheets, sheet-controlled devices between the arm and frame for raising said frame and supporting it from the arm, mechanism for raising and independently supporting the frame, and means for returning the raising devices to inactive position when the frame is raised, substantially as described.

812,231. LUBRICATOR. CHARLES C. DODGE, Bloomfield, N. J., assignor to the Dodge Lubricator Company, Boston, Mass., a Corporation of Massachusetts. Filed Nov. 20, 1904. Serial No. 234,736.

Claim.—1. In a lubricator such as described the combination with a reservoir for the lubricant having a plurality of discharge-ducts, of a rotary pump-carrier and pump located in the reservoir in position to be submerged in the lubricant and having a duct adapted to register successively with the first-mentioned ducts, fixed projections for operating the pump and means for rotating the carrier

2. In a lubricator such as described the combination with a reservoir for the lubricant having a plurality of discharge-duct openings, of a rotary pump-carrier located in the reservoir in position to be submerged in the lubricant and seated over said openings for closing the same, a pump in the carrier, there being a duct from said pump adapted to register successively with the said openings and means for rotating the carrier and operating the pump; substantially as described.

3. In a lubricator such as described, the combination with a reservoir for the lubricant having a plurality of discharge-duct openings, of a rotary carrier located in the reservoir in position to be submerged in the lubricant and seated over said openings to close the same, a pump in said carrier, there being a duct leading to the pump and normally open to the reservoir but adapted to register with the openings in succession and means for rotating the carrier and operating the pump; substantially as described.



4. In a force-feed lubricator the combination with the reservoir having a seat therein formed by projections constituting the terminals of discharge-ducts, of a rotary pump-carrier mounted on said seat to close the openings, a pump on the carrier, there being a pump-duct normally open to the reservoir but adapted to be brought into registry with the openings by the rotation of the carrier, means for rotating the carrier and operating the pump; substantially as described.

5. In a force-feed lubricator the combination with the reservoir having the annular conical seat therein and openings in said seat constituting the terminals of discharge-ducts, of a rotary pump-carrier having a conical working face having its bearing in said seat, a pump in said carrier, there being a pump-duct leading out through the working face of the carrier, means for rotating the carrier and for operating the pump; substantially as described.

6. In a force-feed lubricator, the combination with the reservoir having the annular conical seat therein with projections constituting the terminals of discharge-ducts, of a rotary pump-carrier having a conical working face having its bearing in said seat, a pump in said carrier, there being a pump-duct normally open to the reservoir between the projections but adapted to be brought into registry with the openings by the rotation of the carrier, means for rotating the carrier and operating the pump; substantially as described.

7. In a force-feed lubricator the combination with the base having the discharge-duct terminals therein, the rotary pump-carrier and pump and the drive-gear for the carrier all journaled in the base and the projections for operating the pump mounted on the base, of the removable casing carried by the base and constituting the reservoir for the lubricant; substantially as described.

8. A force-feed lubricator embodying a separable base and casing constituting the reservoir, of a pump mechanism located within the reservoir and supported together with its operating mechanism entirely on the base and independently of the casing; whereby the casing and base may be separated without disturbing the pump mechanism; substantially as described.

9. In a force-feed lubricator such as described, the combination with the reservoir, having discharge-ducts, reciprocatory pump, operating devices therefor and rotary carrier on which the pump and operating devices are mounted, controlling the communication between the pump and discharge-ducts, of means for rotating the carrier, a fixed ring having projections thereon for retracting the pump-plunger and a spring for advancing the pump-plunger; substantially as described.

10. In a force-feed lubricator such as described, the combination with the reservoir and rotary pump-carrier mounted in the reservoir, of a horizontally-arranged pump in said carrier, a horizontal operating-stem for the pump-plunger and fixed projections in the reservoir with which said stem cooperates to control the said plunger; substantially as described.

11. In a force-feed lubricator, the combination with the reservoir having a base, with an apertured seat in said base and a rotary carrier taking its bearing in said seat, of a pump in the carrier having

a discharge-duct adapted to register with said apertures, a spider having arms secured to the base, a spring interposed between the spider and carrier and means for rotating the carrier and operating the pump; substantially as described.

12. In a force-feed lubricator, the combination with the reservoir having a base with an apertured seat in said base and a rotary carrier taking its bearing in said seat, of a pump in the carrier, a spring for advancing the plunger of the pump, a controlling-ring having projections for retracting the plunger of the pump and removably secured in the base, a spring for holding the carrier down and a discharge-duct for the pump adapted to register with the apertures in the seat; substantially as described.

13. In a force-feed lubricator the combination with the reservoir having a base provided with an annular conical seat having discharge-apertures therein, of a rotary carrier having a central bearing and conical working face fitting the conical seat, a pump in said carrier having a discharge-duct adapted to register with the apertures in the seat, fixed annular controlling-ring having projections, a spring-pressed pump-plunger stem coöperating with said projections and a worm and gear for rotating the carrier; substantially as described.

14. A force-feed lubricator having an annular seat projecting on the inner side of its base, with discharge-apertures in said seat, a rotary carrier taking its bearing on said seat and center bearings for said carrier located entirely within the reservoir, gearing for rotating the carrier also located within the reservoir, a reciprocatory pump in the carrier, there being a discharge-duct for the pump adapted to register with the openings in the seat, a spring for advancing the pump-plunger and fixed projections within the reservoir for retracting the pump-plunger against the tension of its spring, the number of said projections corresponding to the number of discharge-openings in the seat; substantially as described.

15. In a force-feed lubricator, the combination with a reservoir, having a plurality of separated projections constituting the terminals of discharge-ducts, of a rotary pump-carrier bearing against said projections, a pump in said carrier, there being a pump-duct normally open to the reservoir between said projections but adapted to register successively with said terminals as the carrier rotates, and instrumentalities for rotating the carrier and operating the pump.

16. In a force-feed lubricator, the combination with a reservoir, having a plurality of separated projections constituting the terminals of discharge-ducts and arranged substantially in a circle, of a rotary carrier seated against said projections, a pump carried by said carrier, and having a duct adapted to register alternately and successively with the spaces between said projections and said terminals, a pump communicating with said duct, means for rotating the carrier, fixed projections for operating the pump-plunger in one direction, and a spring for operating said plunger in the opposite direction.

17. In a force-feed lubricator, the combination with the reservoir having a circular series of discharge-duct openings, of a rotary carrier journaled on a vertical axis in the reservoir, to normally seat over and close said discharge-duct openings, a pump-barrel in said carrier and having an inlet-outlet passage adapted to register successively with the series of openings aforesaid, means for rotating the carrier, a pump-plunger in said barrel and means for reciprocating the same, a spring for holding the carrier down to its seat in the reservoir and a fixed part for maintaining the tension of the spring; substantially as described.

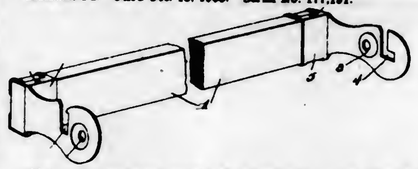
18. In a lubricator such as described, the combination with the reservoir having a plurality of discharge-duct openings arranged in a circular series, of a rotary pump-carrier located in the reservoir in position to be submerged in the lubricant and having a duct adapted to register with the first-mentioned openings, a central bearing at the lower end of the carrier and a spring for holding the carrier down to its seat; substantially as described.

19. In a lubricator such as described, the combination with the reservoir, a rotary pump-carrier having a central journal, fixed supports for the journal located respectively above and below the carrier, projections in the reservoir having discharge-duct openings therein, a pump located in the carrier and having an inlet-outlet opening adapted to register successively with the said discharge-openings, means for rotating the carrier and means for operating the pump; substantially as described.

20. In a lubricator such as described, a reservoir, a rotary carrier mounted therein on central supporting means held by fixed parts above and below the carrier, there being a circular series of discharge-duct openings in the bottom of the reservoir, a pump in the carrier having an inlet-outlet opening adapted to register successively with the discharge-duct openings, means for rotating the carrier and means for operating the pumps; substantially as described.

21. In a lubricator such as described, the combination with a reservoir for the lubricant having a plurality of discharge-ducts, a pump-carrier located in the reservoir in position to be submerged in the lubricant and having a duct adapted to communicate successively with the first-mentioned ducts, a horizontally-arranged pump in the carrier and horizontally-projecting cam-surfaces for operating the pump.

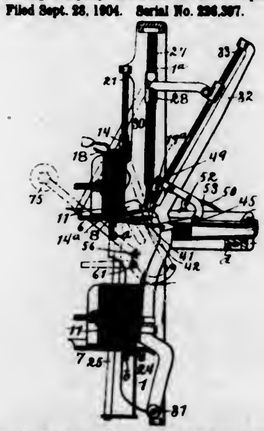
812,262. WINDOW-SHADE BRACKET. ABRAM B. DUNKLE, Stockton, Pa. Filed Oct. 15, 1903. Serial No. 177,191.



Claim.—1. As a new article of manufacture, a window-shade bracket having roller-engaging means and provided with an elongated base-plate, the upper end of which is bent in readiness to be suspended on a supporting strip or bar, the lower end of said base-plate being weakened by the removal of a portion of the metal to form a bar or strip that may be bent by the fingers in a direction transverse of the length of the base.

2. As a new article of manufacture, a window-shade bracket formed of a piece of sheet metal bent to form an elongated base, and a shade-roller-supporting arm at an angle to the base, one end of the base, from a point adjacent to the juncture of the latter with the arm, being bent in readiness to engage a supporting strip or bar, and the opposite end of the base being weakened by cutting away a portion of the metal, thereby to form a manually-bendable portion, substantially as specified.

812,263. ENVELOP-SEALING MACHINE. CHARLES J. FANCHER and HUBERT S. FARNELER, West Granby, Conn., assignors to Simplex Manufacturing Company, Hartford, Conn., a Corporation of Connecticut. Filed Sept. 28, 1904. Serial No. 226,307.



Claim.—1. In an envelop-sealing-machine, horizontal envelop supports or platforms arranged at different levels and means to remove individual envelops from one such platform and permit the same to pass by gravity to another.

2. In an envelop-sealing machine, horizontal envelop-retaining means arranged at different levels, means to remove individual envelops from one such level and permit the same to pass by gravity to another, and means to moisten the envelop-flaps during the transfer.

3. In an envelop-sealing machine, envelop supports or platforms arranged at different levels, means to remove individual envelops from one such platform and permit the same to pass by gravity to another, and means to moisten the envelop-flaps during the transfer from one platform to the other and while leaving the first.

4. In an envelop-sealing machine, horizontal envelop-retaining means arranged at different levels and means to remove individual envelops from one such level and permit the same to pass by gravity to another.

5. In an envelop-sealing machine, envelop supports or platforms arranged at different levels, means to remove individual envelops from one such platform and permit the same to pass by gravity to another, means to moisten the envelop-flaps during the transfer from one platform to another and while leaving the first, and means to seal the envelops by compression.

6. The combination, in an envelop-sealing machine, with a platform and a follower thereon tensioned in one direction, of a reciprocating plate adapted to constantly limit the movement of said follower in the direction of the force exerted by the tension means, the movement permitted said plate being such that its lower edge never rises above the level of the top of the follower or passes below the level of the bottom thereof.

7. The combination, in an envelop-sealing machine, with a platform, a spring-pressed follower thereon, and a reciprocating plate adapted to limit the movement of said follower in the direction of the force exerted by the spring, of a pivotally-mounted confining device adapted to rest upon and hold in place one or more envelops on said platform between the follower and plate and adjacent the latter, during the upward movement of the plate.

8. The combination, in an envelop-sealing machine, with a platform upturned at its front edge, and a follower on said platform, of a reciprocating plate operating above such upturned edge.

9. The combination, in an envelop-sealing machine, with a platform having an upturned edge, and an auxiliary platform or strip extending forward of such edge, of a follower on the first-mentioned platform, and a reciprocating plate in front of said follower.

10. The combination, in an envelop-sealing machine, with a platform and a follower, of a combined envelop stop and flap-opener in front of said follower, and means to reciprocate such combined stop and flap-opener only between the adjacent edge or end of said platform and some point below the level of the upper edge of the follower.

11. In an envelop-sealing machine, the combination with a platform having a follower thereon, and stop-fingers adapted to operate in front of said follower, of guide members, slides mounted on such members, bars connecting said fingers and slides, and means to reciprocate the slides, substantially as set forth.

12. In an envelop-sealing machine, the combination with a platform having a follower thereon, and stop-fingers adapted to operate in front of said follower, of guide members, slides mounted on such members, bars connecting said fingers and slides, arms pivotally mounted at their lower terminals, a presser-plate carried by such arms in front of the follower, operating means for said arms located above said plate, and means to reciprocate said slides and actuate such operating means, substantially as set forth.

13. The combination, in an envelop-sealing machine, with two platforms one above the other, and followers on said platforms, of a reciprocating stop-plate in front of the upper follower, reciprocating stop-fingers in front of the lower follower, and means to simultaneously actuate such reciprocating members.

14. In an envelop-sealing machine, two platforms, one above the other, reciprocating members at or adjacent the front ends of said platforms, and operating mechanism adapted to actuate said reciprocating members in each direction, during one cycle of the mechanism, with a rest between each movement of the reciprocating members.

15. In an envelop-sealing machine, two platforms, one above the other, reciprocating members at or adjacent the front ends of said platforms, operating mechanism adapted to actuate said reciprocating members in both directions, during one cycle on the mechanism, with a pause between each movement of the reciprocating members, and means to cause the latter to be fixed or locked during such pauses.

16. The combination, in an envelop-sealing machine, with a reciprocating stop and flap-opening plate, and reciprocating stop-fingers to assist in holding the envelops after being sealed, of actuating mechanism for such reciprocating members, trips connected with such mechanism, and a crank-arm adapted to sequentially engage and release said trips.

17. The combination, in an envelop-sealing machine, with a reciprocating stop and flap-opening plate, and reciprocating stop-fingers to assist in holding the envelops after being sealed, of actuating mechanism for such reciprocating members consisting of a shaft, a trip-arm on said shaft, a stud, a second trip-arm on said stud, a train of pinions between said shaft and stud, and a crank-arm adapted to sequentially engage and release said trip-arms.

18. In an envelop-sealing machine, the combination with a platform and a follower thereon, of arms pivotally mounted at their lower terminals, a presser-plate carried by such arms in front of said follower, operating means for said arms located above said plate, and means to actuate such operating means, substantially as and for the purpose set forth.

19. In an envelop-sealing machine, the combination with a platform and a follower thereon, of reciprocating stop-fingers adapted to operate in front of said follower, arms pivotally mounted at their lower terminals, a presser-plate carried by such arms in front of the follower and provided with slots opposite said fingers, operating means for said arms located above said plate, and means to actuate such operating means, substantially as and for the purpose set forth.

20. In an envelop-sealing machine, a continuously-reciprocating and intermittently-oscillating wiper and an intermittently-reciprocating wiper-support.

21. In an envelop-sealing machine, a continuously-reciprocating and intermittently-oscillating wiper, a reservoir provided with exposed absorbent material, and an intermittently-reciprocating wiper-support, said wiper being adapted to alternately contact with said absorbent material and said support.

22. In an envelop-sealing machine, a continuously-reciprocating wiper, an intermittently-reciprocating wiper-support, and means to cause said wiper to forcibly fall upon said support.

23. In an envelop-sealing machine, a continuously-reciprocating and intermittently-oscillating wiper, a reciprocating wiper-support, and means to cause said wiper to be withdrawn from said support by a dragging movement.

24. In an envelop-sealing machine, a continuously-reciprocating and intermittently-oscillating wiper, a reservoir located at the front of the machine, having exposed absorbent material therein, and means to cause said wiper when in its forward position to forcibly fall upon such material.

25. In an envelop-sealing machine, a continuously-reciprocating and intermittently-oscillating wiper, a reservoir located at the front of the machine, having exposed absorbent material therein, and means to cause said wiper, as it approaches the end of its forward movement, to be dragged over such material.

26. The combination, in an envelop-sealing machine, with a vertically-reciprocating flap-opener, of a continuously-reciprocating and intermittently-oscillating wiper, and an intermittently-reciprocating wiper-support.

27. The combination, in an envelop-sealing machine, with a vertically-reciprocating flap-opening plate provided with a forwardly-extending beak, of a continuously-reciprocating and intermittently-oscillating wiper and an intermittently-reciprocating wiper-support, both being adapted to move back adjacent to said plate and said wiper being adapted to pass both sides of said beak.

28. The combination, in an envelop-sealing machine, with a reciprocating flap-opener, of a wiper and a wiper-support, means to move said wiper and support into a position immediately adjacent said flap-opener, the wiper and support being separated and again united during such movement, and means to elevate the flap-opener while the wiper and support are adjacent thereto.

29. In an envelop-sealing machine, a vertically-reciprocating depressor, and a horizontally-reciprocating wiper and wiper-support, the depressor and the wiper with its support being adapted to cross each other's paths of travel.

30. The combination, in an envelop-sealing machine, of a vertically-reciprocating depressor, a horizontally-reciprocating wiper and wiper-support, and means to elevate said depressor during the rearward movement of said wiper and its support and to withdraw the wiper and its support from beneath the depressor when the latter descends.

31. In an envelop-sealing machine, a vertically-reciprocating flap-opener, a vertically-reciprocating depressor, and a horizontally-reciprocating wiper and wiper-support adapted to play back and forth in front of the plane of said flap-opener beneath said depressor when the latter is elevated.

32. In an envelop-sealing machine, an intermittently vertically reciprocating flap-opener, a continuously-reciprocating depressor, and a horizontally-reciprocating wiper and wiper-support adapted to pass beneath said depressor when elevated, into contiguity with said flap-opener when depressed.

33. In an envelop-sealing machine, a reciprocating flap-opening plate provided with a forwardly-extending beak, and a reciprocating depressor operating in front of said beak.

34. In an envelop-sealing machine, an intermittently-reciprocating flap-opener, a continuously-reciprocating depressor, and means to elevate said depressor while said flap-opener is down and to depress the depressor while the flap-opener is in its elevated position.

35. The combination, in an envelop-sealing machine, of a slidingly-mounted wiper, a slidingly-mounted wiper-support, resilient

connections between said wiper and support, stops arranged to limit the movement of the support in one direction, and means to directly actuate the wiper.

36. The combination, in an envelop-sealing machine, with cams, of a slidingly-mounted wiper provided with cam-engaging members arranged to ride over said cams, to raise the wiper and to pass beneath the same.

37. The combination, in an envelop-sealing machine, with cams and supports for the same, said cams being adapted to be elevated at one end from said supports, of a slidingly-mounted wiper provided with cam-engaging members adapted to ride over said cams, to raise the wiper, and to pass under and out beneath the free ends of the cams.

38. The combination, in an envelop-sealing machine, of a frame provided with guide members, arms pivoted at their bases to said frame, provided with obliquely-directed guide members and carrying a presser-plate adapted to assist in sealing the envelops, sliding connections between the frame-guide members and the arm-guide members, and means to reciprocate said sliding connections on the guide members.

39. The combination, in an envelop-sealing machine, with a frame provided with guide members, of arms provided with obliquely-directed guide members and carrying a presser-plate adapted to assist in sealing the envelops, and sliding connections between the frame-guide members and the arm-guide members, through the medium of which said arms and presser-plate are oscillated when said connections are reciprocated on the guide members.

40. The combination, in an envelop-sealing machine, of a frame provided with guide members, arms pivoted at their bases to said frame and provided with obliquely-directed guide members, sliding connections between the frame-guide members and the arm-guide members to oscillate said arms when said connections are reciprocated on the guide members, and wiper mechanism connected with and reciprocated by the arms.

41. The combination, in an envelop-sealing machine, of a frame provided with guide members, arms pivoted at their bases to said frame, provided with obliquely-directed guide members and carrying a presser-plate adapted to assist in sealing the envelops, and sliding connections between the frame-guide members and the arm-guide members to oscillate said arms and plate when said connections are reciprocated on the guide members.

42. The combination, in an envelop-sealing machine, of a frame provided with guide members, arms pivoted at their bases to said frame, provided with obliquely-directed guide members and carrying a presser-plate adapted to assist in sealing the envelops, sliding connections between the frame-guide members and the arm-guid members to oscillate said arms and plate when said connections are reciprocated on the guide members, and horizontally-reciprocating wiper mechanism connected with the arms.

43. The combination, in an envelop-sealing machine, with a frame provided with guide members, arms pivoted at their bases to said frame, provided with obliquely-directed guide members and carrying a presser-plate adapted to assist in sealing the envelops, and sliding connections between the frame-guide members and the arm-guide members, of a shaft journaled in the frame, crank-arms on said shaft, and links connecting said crank-arms with said sliding connections.

44. An envelop-sealing machine, comprising means to retain an envelop in a substantially upright position, such means consisting of a support for the lower edge of the envelop, a forwardly-tensioned support at the back and a rising and falling support at the front, and other means to engage the sealing-flap of the envelop to withdraw said envelop from the retaining means.

45. An envelop-sealing machine, comprising means to retain an envelop in a substantially upright position, such means consisting of a support for the lower edge of the envelop, a forwardly-tensioned support at the back and a rising and falling support at the front, and other means to engage the sealing-flap of the envelop to withdraw said envelop from the retaining means and for moistening the flap.

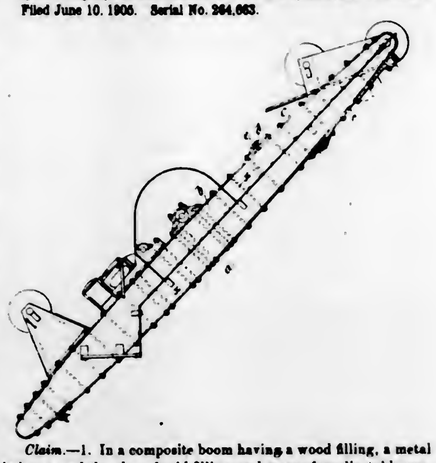
46. An envelop-sealing machine, comprising means to retain an envelop in a substantially upright position, such means consisting of a support for the lower edge of the envelop, a forwardly-tensioned support at the back and a rising and falling support at the front, and other means to engage the sealing-flap of the envelop to withdraw said envelop from the retaining means and for moistening the flap, and additional means for sealing the flap.

47. In an envelop-sealing machine, a vertically-reciprocating depressor, and a horizontally-reciprocating wiper and envelop-flap support, the depressor and the support being adapted to cross each other's paths of travel.

48. In an envelop-sealing machine, a reciprocating wiper for the inner side of the flap, a reciprocating support for the flap and wiper, means to cause said wiper and support to move in the same directions, the former traveling farther than he latter, and means to cause the wiper to fall upon the support or the inner side of the flap thereon.

49. In an envelop-sealing machine, a reciprocating wiper for the inner side of the flap, a reciprocating support for the flap and wiper, and means to cause said wiper to travel in the same direction with said support for a greater distance than the support.

812,264. COMPOSITE BOOM FOR STEAM-SHOVELS AND THE LIKE. WALTER FERRIS, South Milwaukee, Wis., assignor to The Bucyrus Company, South Milwaukee, Wis., a Corporation of Wisconsin. Filed June 10, 1905. Serial No. 264,663.



Claim.—1. In a composite boom having a wood filling, a metal binder around the edge of said filling, and means for adjustably connecting the ends of said binder.

2. In a composite boom having a wood filling, a sectional metal binder around the edges of said filling, and means for adjustably connecting the adjacent ends of the binder-sections.

3. In a composite boom having a wood filling, a metal binder around the edge of said filling, lugs on the ends of said binder and bolts coöperating with said lugs for adjustably connecting the ends of the binder.

4. In a composite boom having a wood filling, sectional metal binding-plates around the edge of said filling, lugs on the ends of the plate-sections, and bolts coöperating with adjacent lugs for adjustably connecting the plates.

5. In a composite boom having a wood filling and metal side and edge plates, a boom-guy lug attached to the under side of the boom, engaging and supporting the side and edge plates.

6. In a composite boom having a wood filling and metal side and edge plates, a boom-guy lug attached to the under side of the boom, engaging and supporting the side and edge plates, said lug comprising a strap having a pin-bearing thereon and vertical flanges along the edges of said strip.

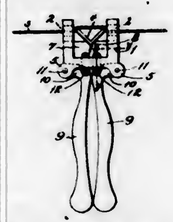
7. In a composite boom having a wood filling and metal side and edge plates, a boom-guy lug comprising a strap riveted to the edge plate below the point-sheave, a pin-bearing on said strap and flanges along the sides of said strap engaging the edges of the side plates.

812,265. WIRE-FENCE TOOL. HENRY HAMMERMEISTER, Millersport, Ohio. Filed Sept. 9, 1905. Serial No. 277,751.

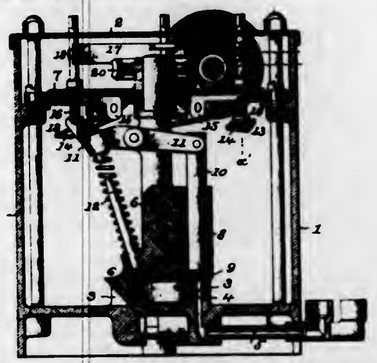
Claim.—1. A wire-fence tool comprising a drawing-head provided with wire-engaging means, a cross-bar movably mounted in the head adapted to form a fixed bearing for the head, and oppositely-movable operating-levers having pivotal connection with the head and the cross-bar.

2. A wire-fence tool comprising a drawing-head provided with wire-engaging teeth, a cross-bar on which the head is slidably mounted, oppositely-movable hand-levers pivotally connected with the bar, and links pivotally connected with the levers and the cross-bar.

3. A wire-fence tool comprising a substantially U-shaped drawing-head provided with a plurality of wire-engaging teeth, a cross-bar on which the head is slidably mounted provided with a post-receiving notch, hand-levers having offset ends connected to the bar, and toggle-links having pivotal connection with the cross-bar and the levers.



812,266. PUMPING APPARATUS. CHRISTIAN C. HILL, Chicago, Ill.; Clothilde B. Hill, executrix of said Christian C. Hill, deceased, assignor to The Steel Ball Company, Chicago, Ill., a Corporation of Wisconsin. Filed Dec. 23, 1904. Serial No. 238,046.



Claim.—1. A pumping apparatus, comprising a stationary member carrying a circular cluster of bearing-lugs in spaced relation and formed with outlet-passages in their bearing-faces, a revoluble head having bearing at one end on said bearing-lugs, there being a pump-cylinder carried by said head and having an inlet-outlet passage adapted to alternately register with the spaces between said lugs and with the outlet-passages therein, means for revolving said head, a pump-plunger in said cylinder, and means for reciprocating said plunger, substantially as set forth.

2. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end on said member, there being a pump-cylinder carried by said head and having an inlet-outlet passage adapted to serially register with the series of outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder and means for reciprocating said plunger, the same comprising a circular series of cams equal in number to the series of outlet-passages, means for effecting an individual adjustment of said cams, and an intermediate operative connection between the said cams and the pump-plunger, substantially as set forth.

3. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end on said member, there being a pump-cylinder carried by said head and having an inlet-outlet passage adapted to serially register with the series of outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder, and means for reciprocating said plunger, the same comprising a circular series of cams equal in number to the series of outlet-passages, a series of individual screws for effecting independent adjustment of said cams, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

4. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end on said member, there being a pump-cylinder carried by said head and having an inlet-outlet passage adapted to serially register with the series of outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder and means for reciprocating said plunger, the same comprising a circular series of cams on said spider equal in number to the series of outlet-passages, means for effecting an individual adjustment of said cams, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

5. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end on said member, a stationary spider forming a bearing for the other end of the head, there being a pump-cylinder carried by said head and having an inlet-outlet passage adapted to serially register with the series of outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder and means for reciprocating said plunger, the same comprising a circular series of cams on said spider equal in number to the series of outlet-passages, means for effecting an individual adjustment of said cams, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

6. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end on said member, a stationary spider forming a bearing for the other end of the head, there being a pump-cylinder carried by said head and having an inlet-outlet passage adapted to serially register with the series of outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder and means for reciprocating said plunger, the same comprising a circular series of cams on said spider equal in number to the series of outlet-passages, a series of individual screws for effecting individual adjustment of said cams, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

7. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end on said member, a stationary spider forming a bearing for the other end of the head, there being a pump-cylinder carried by said head and having an inlet-outlet passage adapted to serially register with the series of outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder and means for reciprocating said plunger, the same comprising a circular series of cams on said spider equal in number to the series of outlet-passages, a series of individual screws for effecting individual adjustment of said cams, a yoke-piece provided with resilient eyes for frictional engagement with the shanks of said screws, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

8. A pumping apparatus, comprising a stationary member carrying a circular cluster of bearing-lugs in spaced relation and formed with outlet-passages in their bearing-spaces, a revoluble head having bearing at one end on said bearing-lugs, there being a pump-cylinder arranged at one side of the axis of rotation of said head and having an inlet-outlet passage adapted to alternately register with the spaces between said lugs and with the outlet-passages therein, means for revolving said head, a pump-plunger in said cylinder, and means for reciprocating said plunger, substantially as set forth.

9. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end in said member, there being a pump-cylinder arranged at one side of the axis of rotation of said head and having an inlet-outlet passage adapted to serially register with the outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder, and means for reciprocating said plunger, the same comprising a circular series of cams equal in number to the series of outlet-passages, means for effecting an individual adjustment of said cams, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

10. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end in said member, there being a pump-cylinder arranged at one side of the axis of rotation of said head and having an inlet-outlet passage adapted to serially register with the outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder, and means for reciprocating said plunger the same comprising a circular series of cams equal in number to the series of outlet-passages, a series of individual screws for effecting independent adjustment of said cams, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

11. A pumping apparatus, comprising a stationary member

provided with a circular series of outlet-passages, a revoluble head having bearing at one end in said member, there being a pump-cylinder arranged at one side of the axis of rotation of said head and having an inlet-outlet passage adapted to serially register with the outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder, and means for reciprocating said plunger the same comprising a circular series equal in number to the series of outlet-passages, a series of individual screws for effecting independent adjustment of said cams, a yoke-piece provided with a series of resilient eyes having frictional engagement with the shanks of said screws, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

12. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end on said member, a stationary spider forming a bearing for the other end of the head, there being a pump-cylinder arranged at one side of the axis of rotation of said head and having an inlet-outlet passage adapted to serially register with the series of outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder and means for reciprocating said plunger, the same comprising a circular series of cams on said spider equal in number to the series of outlet-passages, means for effecting an individual adjustment of said cams, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

13. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end on said member, a stationary spider forming a bearing for the other end of the head, there being a pump-cylinder arranged at one side of the axis of rotation of said head and having an inlet-outlet passage adapted to serially register with the series of outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder and means for reciprocating said plunger, the same comprising a circular series of cams on said spider equal in number to the series of outlet-passages, a series of individual screws for effecting independent adjustment of said cams, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

14. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end on said member, a stationary spider forming a bearing for the other end of the head, there being a pump-cylinder arranged at one side of the axis of rotation of said head and having an inlet-outlet passage adapted to serially register with the series of outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder and means for reciprocating said plunger, the same comprising a circular series of cams on said spider equal in number to the series of outlet-passages, a series of individual screws for effecting independent adjustment of said cams, a yoke-piece provided with resilient eyes for frictional engagement with the shanks of said screws, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

15. A pumping apparatus, comprising a stationary member carrying a circular cluster of bearing-lugs in spaced relation and formed with outlet-passages in their bearing-faces, a revoluble head having bearing at one end on said bearing-lugs, there being a pump-cylinder carried by said head and having an inlet-outlet passage adapted to alternately register with the spaces between said lugs and with the outlet-passages therein, means for revolving said head, a pump-plunger in said cylinder, a spring for moving said plunger in one direction and a cam mechanism for moving said plunger in the other direction, substantially as set forth.

16. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end on said member, there being a pump-cylinder carried by said head and having an inlet-outlet passage adapted to serially register with the series of outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder, a spring for moving said plunger in one direction and a cam mechanism for moving said plunger in the other direction, the same comprising a circular series of cams equal in number to the series of outlet-passages, means for effecting an individual adjustment of said cams, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

17. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end on said member, there being a pump-cylinder carried by said head and having an inlet-outlet passage adapted to serially register with the series of outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder, a spring for moving said plunger in one direction and a cam mechanism for moving said plunger in the other direction, the same comprising a circular series of cams equal in number to the series of outlet-passages, a series of individual screws for effecting independent adjustment of said cams, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

18. A pumping apparatus comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end on said member, a stationary spider forming a bearing for the other end of the head, there being a pump-cylinder carried by said head and having an inlet-outlet passage adapted to serially register with the series of outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder, a spring for moving said plunger in one direction, and a cam mechanism for moving said plunger in the other direction, the same comprising a circular series of cams equal in number to the series of outlet-passages, means for effecting an individual adjustment of said cams, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

19. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end on said member, a stationary spider forming a bearing for the other end of the head, there being a pump-cylinder carried by said head and having an inlet-outlet passage adapted to serially register with the series of outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder, a spring for moving said plunger in one direction, and a cam mechanism for moving said plunger in the other direction, the same comprising a circular series of cams equal in number to the series of outlet-passages, a series of individual screws for effecting said independent adjustment of said cams, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

20. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end in said member, there being a pump-cylinder arranged at one side of the axis of rotation of said head and having an inlet-outlet passage adapted to serially register with the outlet-passages aforesaid, means for revolving said head, a spring for moving said plunger in one direction, and a cam mechanism for moving said plunger in the other direction, the same comprising a circular series of cams equal in number to the series of outlet-passages, means for effecting an individual adjustment of said cams, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

21. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end in said member, there being a pump-cylinder arranged at one side of the axis of rotation of said head and having an inlet-outlet passage adapted to serially register with the outlet-passages aforesaid, means for revolving said head, a spring for moving said plunger in one direction, and a cam mechanism for moving said plunger in the other direction, the same comprising a circular series of cams equal in number to the series of outlet-passages, a series of individual screws for effecting independent adjustment of said cams, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

22. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end on said member, a stationary spider forming a bearing for the other end of the head, there being a pump-cylinder arranged at one side of the axis of rotation of said head and having an inlet-outlet passage adapted to serially register with the series of outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder, a spring for moving said plunger in one direction, and a cam mechanism for moving said plunger in the other direction, the same comprising a circular series of cams on said spider equal in number to the series of outlet-passages, means for effecting an individual adjustment of said cams, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

23. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end on said member, a stationary spider forming a bearing for the other end of the head, there being a pump-cylinder arranged at one side of the axis of rotation of said head and having an inlet-outlet passage adapted to serially register with the series of outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder, a spring for moving said plunger in one direction, and a cam mechanism for moving said plunger in the other direction, the same comprising a circular series of cams equal in number to the series of outlet-passages, a series of individual screws for effecting independent adjustment of said cams, and an intermediate operative connection between said cams and the pump-plunger, substantially as set forth.

24. A pumping apparatus, comprising a stationary member provided with a circular series of outlet-passages, a revoluble head having bearing at one end on said member, a stationary spider forming a bearing for the other end of the head, there being a pump-cylinder carried by said head and having an inlet-outlet passage adapted to serially register with the series of outlet-passages aforesaid, means for revolving said head, a pump-plunger in said cylinder and means for reciprocating said plunger, and a spring arranged between said spider and a collar on the revoluble head and adapted to hold said head to its bearing on the stationary member, substantially as set forth.

812,267. **HORSE FLY-NET.** ALBERT HOST, Wellston, Ohio. Filed July 22, 1905. Serial No. 270,351.

Claim.—1. In a harness, the combination with the back-strap, breeching and quarter-straps, each provided with orifices, of fly-net lashes threaded through the orifices of the respective straps and held against movement relatively thereto.

2. The combination with the overcheck-strap, back-strap, breeching-strap and quarter-straps of a harness, of fly-net lashes threaded therethrough.

812,268. **COFFEE-ROASTING MACHINE.** FRANK T. HOLMES, Brooklyn, N. Y., assignor of one-half to Huntley Manufacturing Company, Silvercreek, N. Y. Filed July 12, 1905. Serial No. 269,310.

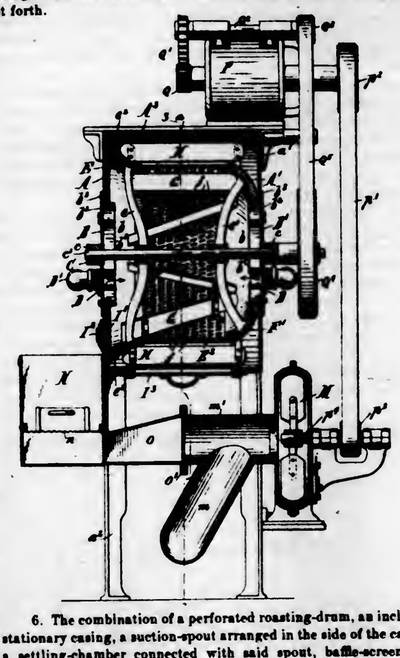
Claim.—1. The combination of a perforated revolving drum, means for heating the same, an inclosing stationary casing, a suction-spout arranged in the side of the casing, lengthwise of the drum, and wings on the drum which sweep through the space between the drum and the casing and carry the chaff to said suction-spout, substantially as set forth.

2. The combination of a perforated revolving drum, means for heating the same, an inclosing stationary casing, a suction-spout arranged in the side of the casing, lengthwise of the drum, and at the descending side of the same, wings on the drum which sweep through the space between the drum and the casing and carry the chaff to the suction-spout, a settling-chamber with which said spout is connected, and an exhaust-fan connected with said chamber, substantially as set forth.

3. The combination of a perforated, revolving, open-ended drum, a burner projecting a flame into the same, an inclosing stationary casing, a suction-spout arranged in the side of the lower portion of the casing and extending lengthwise of the drum, and a suction-fan connected with said spout, substantially as set forth.

4. The combination of a stationary inclosing casing having its front and rear heads provided with open annular frames for the admission of air and having a guard-flange on the inner side of the front head, and a perforated roasting-drum having its front end arranged adjacent to said guard-flange and having its rear end constructed to fit around the adjacent annular frame, substantially as set forth.

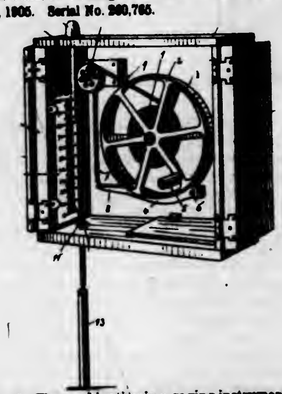
5. The combination of a stationary inclosing casing, having its front and rear heads provided with open annular frames for the admission of air and having a guard-flange on the inner side of the front head, a perforated roasting-drum having its front end arranged adjacent to said guard-flange and having its rear end fitted around the adjacent annular frame, a suction-spout connected with said casing, and a suction-fan connected with said spout, substantially as set forth.



6. The combination of a perforated roasting-drum, an inclosing stationary casing, a suction-spout arranged in the side of the casing, a settling-chamber connected with said spout, baffle-screens arranged in said chamber, and a suction-fan connected with said chamber, substantially as set forth.

7. The combination of a perforated roasting-drum, an inclosing stationary casing, a suction-spout arranged in the side of the casing, a settling-chamber connected with said spout, a cooling-chamber for the roasted coffee, a suction-fan, and spouts leading from said settling-chamber and said cooling-chamber to said suction-fan, substantially as set forth.

812,269. **WATER-LEVEL-GAGING INSTRUMENT.** ROBERT H. HORTON, Utica, N. Y., assignor to Daniel L. Mott, Utica, N. Y. Filed May 17, 1905. Serial No. 260,765.



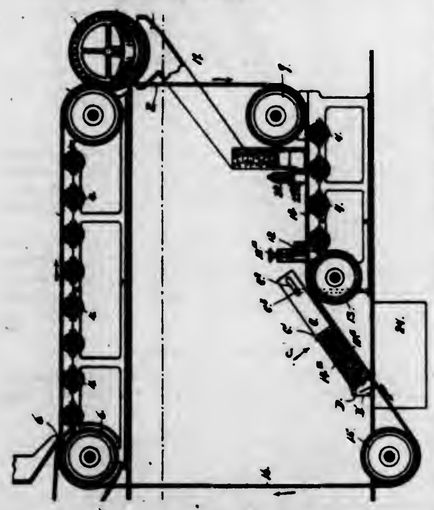
Claim.—1. The combination in a gaging instrument of the character described of a casing arranged to be secured in a fixed position, a scale on the interior of the casing, a graduated gage-chain, a reel in the casing, an opening in the bottom of the casing at the foot of the scale, means for causing the gage-chain to pass from the reel in close proximity to the said scale and through the opening and means for controlling the rotation of the reel, substantially as set forth.

2. The combination in a gaging instrument of a casing adapted to be secured in a fixed position, an adjustable scale in said casing, a reel in said casing and means for controlling the movement of the reel, a graduated gage-chain adapted to be wound on the reel and passing from thence in close proximity to said scale and through an opening in the casing at the foot of the scale, substantially as set forth.

3. The combination in a gaging instrument of the character described of a casing adapted to be secured in a fixed position, a fixed observation-mark within the casing, a reel mounted in the casing, a graduated gage-chain passing in close proximation to said observation-point and thence through an opening in the bottom of the casing, and a gage-chain weight adapted to pass through said opening and be housed in the casing, substantially as set forth.

4. The combination in a gaging instrument of the character described of a casing adapted to be secured in a fixed position, an adjustable scale secured in the casing having a projecting arm extending to the exterior of the casing by means of which the position of the scale can be nicely determined, a reel mounted in the casing, a graduated gage-chain adapted to be wound on the reel and passing in close proximity to the scale and through an opening in the casing at the foot of the scale, a weight arranged on the end of the gage-chain adapted to be passed through said opening and housed in the casing, and means for operating and securing said reel in adjusted position, substantially as set forth.

812,270. ORE-SORTING BELT. FRANK W. JACQUES, Victor, Colo. Filed Jan. 24, 1905. Serial No. 242,534.



Claim.—1. In an ore-belt apparatus, the combination with suitable supporting mechanism, of an endless traveling belt one portion of which is located considerably higher than the other, and suitable means for taking the material discharged from the upper portion of the belt, grading the same, and discharging one grade of it upon the reverse surface of the lower or return portion thereof.

2. The combination with suitable supporting apparatus, of an endless traveling belt so mounted that one portion thereof is considerably higher than the other, the lower or return portion thereof having its reverse surface exposed to receive the ore, means located at the rear extremity of the upper portion of the belt for receiving the discharge from the upper portion of the belt and separating the finer portion therefrom, and means for delivering the said finer portion of the material, upon the lower reverse surface of the belt for the purpose set forth.

3. In ore-belt apparatus, the combination with a suitable support, of an endless traveling belt having one portion higher than the other, a chute for receiving the discharge from the rear extremity of the upper portion of the belt, a rotary grizzly into which the said material is discharged by the chute, and another chute for receiving the finer portion of the material from the grizzly and discharging it upon the reverse side of the lower or return portion of the belt.

4. The combination with a suitable support, of an endless traveling ore-belt having one portion located considerably higher than the other, the lower belt portion being the return portion thereof, having its reverse surface exposed to receive the ore, means for receiving the discharge from the upper portion of the belt and grading the same, and means for delivering one grade of the material to the lower reverse surface of the belt, and a device mounted to set on the material to remove it from the lower portion of the belt for the purpose set forth.

5. The combination with a suitable support, of an endless traveling ore-belt having horizontal upper and lower portions, a part of the lower run being inclined, the upper portion being considerably more elevated than the lower portion, the lower portion having its reverse side exposed to receive the ore, the inclined portion being located at the forward extremity of the lower portion, and a device placed above the inclined portion of the belt whereby the material is automatically discharged therefrom, substantially as described.

6. In an ore-belt apparatus, the combination with suitable supporting mechanism, of an endless traveling belt, one portion of which is located higher than the other, suitable means for taking the material discharged from the upper portion of the belt and discharging it upon the reverse surface of the lower or return portion thereof, means mounted above the lower portion of the belt and adapted to separate the same to facilitate the ore-sorting operation, and means mounted above the lower portion of the belt remote from where the ore is fed to the latter, for removing the material from both sides of the belt, and receptacles mounted on opposite sides of the belt to receive the said discharge, substantially as described.

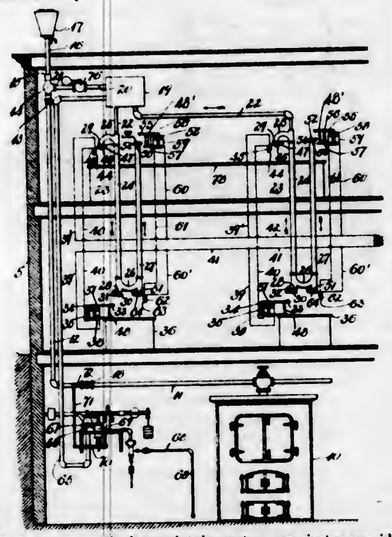
7. In ore-belt apparatus, the combination of an endless traveling belt or apron one portion of which is located above the other, suitable means for taking the material discharged from the upper portion of the belt grading or classifying it and delivering one grade of it to the reverse surface of the lower or return portion thereof, and a device for removing the material from the lower portion of the belt, the said device being located remote from the point of discharge and consisting of inclined wings or blades adapted to remove the material from the belt as the latter travels thereunder, and discharge the same at suitable points on opposite sides.

8. The combination with an endless traveling belt or apron having upper and lower parallel or approximately parallel portions, means for feeding the material to be treated upon the upper surface of the upper part of the belt, means for receiving the discharge from the upper portion of the belt, and delivering it to the reverse side of the lower portion of the belt, and a device mounted above the lower portion of the belt remote from the point of discharge, and consisting of inclined wings occupying a position close to the belt and adapted to remove the material thereon and discharge the same on opposite sides of the belt, and an arm pivoted at the apex or angle of the inclined wings and adapted to swing in either direction, whereby all of the material may be discharged on either side of the belt as desired.

9. In an ore-belt apparatus, the combination of an endless traveling belt or apron one part of which is considerably higher than the other, means for delivering the ore to be treated, to the upper portion of the belt, a rotary grizzly for receiving the discharge from the upper portion of the belt, a chute for receiving the finer material which passes through the grizzly between its extremities, and arranged to discharge the said material upon the lower portion of the belt, a vertically-adjustable spreader located adjacent the point of the discharge and extending transversely of the belt, and a discharge device mounted above the belt remote from the spreader and consisting of stationary inclined wings located to scrape the material from the belt and discharge the same on opposite sides thereof, an arm pivotally connected with the apex or angle of the inclined wings and adapted to be swung in either direction for the purpose of discharging the whole of the material on either side of the belt, and a small V-shaped device located above the central portion of the belt and directly in front of the pivoted arm when in its central position whereby the material upon the belt is prevented from interfering with the action of said arm.

812,271. PNEUMATIC-DESPATCH-TUBE SYSTEM. JOHN S. JACQUES, Dorchester, Mass. Filed May 24, 1905. Serial No. 261,903.

Claim.—1. In a pneumatic-despatch-tube system, an ejector provided with an inlet and an outlet orifice, a despatch-tube provided with an inlet and an outlet orifice, said tube connected to said ejector intermediate said ejector inlet and outlet orifices, a terminal valve adapted to close each of said despatch-tube orifices, respectively, means for normally closing said valves, an electromagnet and a catch adapted to hold one of said terminal valves open and to be operated by said electromagnet, the other of said terminal valves adapted to close the circuit of said magnet and operates said catch to release the valve held thereby.



2. In a pneumatic-despatch-tube system, an ejector provided with an inlet and an outlet orifice, a despateh-tube provided with an inlet and an outlet orifice, said tube connected to said ejector intermediate said ejector inlet and outlet orifices, a terminal valve adapted to close each of said despatch-tube orifices, respectively, means for normally closing said valves and an electromagnet having an armature formed as a catch to engage one of said terminal valves, the other of said terminal valves adapted to close the circuit of said magnet and operate said catch to release the valve held thereby.

3. In a pneumatic-despatch-tube system, an ejector provided with an inlet and an outlet orifice, a transmission and a return tube, each of said tubes provided with an inlet and an outlet orifice, respectively, one of said tubes connected to said ejector intermediate said ejector inlet and outlet orifices, a terminal valve adapted to close each of said tube-outlet orifices, respectively, means for normally closing said valves, a connecting-tube joining said transmission and return tubes together, an electromagnet and a catch adapted to hold one of said terminal valves open, and to be operated by said electromagnet, one of the other of said valves adapted to close the circuit of said magnet and operate said catch to release the valve held thereby.

4. In a pneumatic-despatch-tube system, an ejector provided with an inlet and an outlet orifice, a despatch-tube provided with an inlet and an outlet orifice, a vacuum-reservoir connected to said despatch-tube and to said ejector intermediate the inlet and outlet orifices of said ejector, a terminal valve adapted to close each of said despatch-tube orifices, respectively, means for normally closing said valves, an electromagnet, and a catch adapted to hold one of said terminal valves open, and to be operated by said electromagnet, the other of said valves adapted to close the circuit of said magnet and operate said catch to release the valve held thereby.

5. In a pneumatic-despatch-tube system, an ejector provided with an inlet and an outlet orifice, a despatch-tube provided with an inlet and an outlet orifice, a vacuum-reservoir connected to said despatch-tube and to said ejector intermediate the inlet and outlet orifices of said ejector, a terminal valve adapted to close each of said despatch-tube-outlet orifices, respectively, means for normally closing said valves, an electromagnet, a catch adapted to hold one of said terminal valves open, and to be operated by said electromagnet, the other of said valves adapted to close the circuit of said magnet and operate said catch to release the valve held thereby, and a check-valve located between said vacuum-reservoir and ejector.

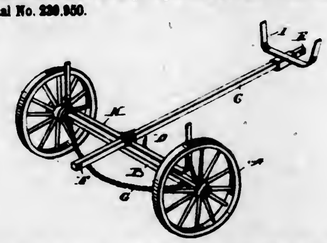
6. In a pneumatic-despatch-tube system, an ejector provided with an inlet and an outlet orifice, a despatch-tube provided with an inlet and an outlet orifice, a vacuum-reservoir connected to said despatch-tube and to said ejector intermediate the inlet and outlet orifices of said ejector, a terminal valve adapted to close each of said despatch-tube orifices, respectively, means for normally closing said valves, an electromagnet, a catch adapted to hold one of said terminal valves open, and to be operated by said electromagnet, the other of said valves adapted to close the circuit of said magnet and operate said catch to release the valve held thereby, and a receptacle adapted to contain steam, air, or the like under pressure connected to the inlet-orifice of said ejector.

7. In a pneumatic-despatch-tube system, an ejector provided with an inlet and an outlet orifice, a vacuum-reservoir connected to said despatch-tube and to said ejector intermediate the inlet and outlet orifices of said ejector, a terminal valve adapted to close each of said despatch-tube orifices, respectively, means for normally closing said valves, an electromagnet, a catch adapted to hold one of said terminal valves open, and to be operated by said electromagnet, the other of said valves adapted to close the circuit of said magnet and operate said catch to release the valve held thereby, a receptacle adapted to contain steam, air, or the like under pressure connected to the inlet-orifice of said ejector, and a throttle-valve interposed between said ejector and receptacle.

8. In a pneumatic-despatch-tube system, an ejector provided with an inlet and an outlet orifice, a despatch-tube provided with an inlet and an outlet orifice, a vacuum-reservoir connected to said despatch-tube and to said ejector intermediate the inlet and outlet orifices of said ejector, a terminal valve adapted to close each of said despatch-tube orifices, respectively, means for normally closing said valves, an electromagnet, a catch adapted to hold one of said terminal valves open, and to be operated by said electromagnet, the other of said valves adapted to close the circuit of said magnet and operate said catch to release the valve held thereby, a receptacle adapted to contain steam, air or the like under pressure connected to the inlet-orifice of said ejector, a throttle-valve interposed between said ejector and receptacle, and mechanism to open and close said throttle-valve.

9. In a pneumatic-despatch-tube system, an ejector provided with an inlet and an outlet orifice, a despatch-tube provided with an inlet and an outlet orifice, a vacuum-reservoir connected to said despatch-tube and to said ejector intermediate the inlet and outlet orifices of said ejector, a terminal valve adapted to close each of said despatch-tube orifices, respectively, means for normally closing said valves, an electromagnet, a catch adapted to hold one of said terminal valves open, and to be operated by said electromagnet, the other of said valves adapted to close the circuit of said magnet and operate said catch to release the valve held thereby, a receptacle adapted to contain steam, air or the like under pressure connected to the inlet-orifice of said ejector, a throttle-valve interposed between said ejector and receptacle, fluid-pressure-controlled mechanism to open and close said throttle-valve, and a pipe operatively connecting said vacuum-reservoir to said mechanism, whereby said mechanism is operated and said throttle-valve opened and closed.

812,272. CORN-SHOCK LOADER AND CARRIER. JOHN D. KAYLOR, Harrison township, Logan county, Ohio. Filed Jan. 6, 1905. Serial No. 239,950.

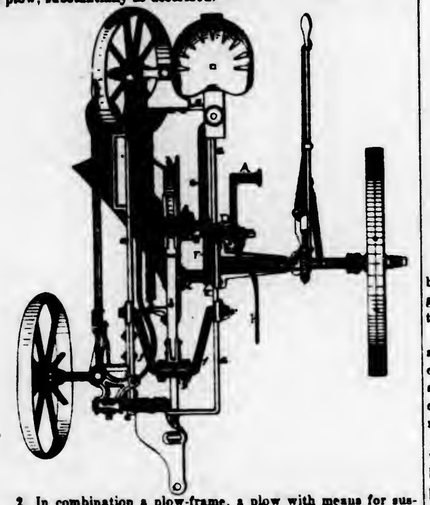


Claim.—1. In a corn-shock loader and carrier, the wheels A, axle B, lever C, chain G, arms K and the arms I, adjustable on the lever to accommodate them to shocks of different length, as and for the purpose set forth.

2. In a corn-shock loader and carrier, the wheels A, axle B, lever C, chain G, arms K adjustable arms I and means for securing several carriers in train, as and for the purpose set forth.

812,273. LIFTING DEVICE FOR GANG AND SULKY PLOWS. FRED J. KELLY, Lansing, Mich., assignor to H. Bement's Sons, Lansing, Mich., a Corporation of Michigan. Filed May 17, 1904. Serial No. 208,480.

Claim.—1. In combination, a plow-frame, a plow with means for suspending the same from the frame, means for raising said plow, an automatically-operable hook pivoted in said lifting means and a stationary lug adapted to be engaged by said hook on the beam of the plow, substantially as described.



2. In combination a plow-frame, a plow with means for suspending the same from the frame, means for raising said plow including a shaft, a lever thereon, a bail between said shaft and plow-beam, a hook pivoted to the shaft and operatively connected to said bail, and a lug adapted to be engaged by said hook attached to the beam of said plow.

3. In combination with a plow and frame from which said plow is adjustably suspended, a lever for raising said plow, a bail connecting said lever with the beam of said plow, a hook pivoted on the shaft of said lever and loosely connected to said bail, and a lug adapted to be engaged by said hook, substantially as described.

4. In combination with a plow and frame from which said plow is adjustably suspended, a lever for raising said plow, mounted on said frame, a bail connecting said lever with the beams of said plow, a hook pivoted on the shaft of said lever means on the hook for engaging said bail and a lug adapted to be engaged by said hook, substantially as described.

5. In combination with a plow and frame from which said plow is adjustably suspended, a lever for raising said plow, a bail connecting said lever with the beam of said plow, a hook pivoted on the shaft of said lever, a lug adapted to be engaged by said hook, and a foot-lever connected to said hook for releasing said clutch, substantially as described.

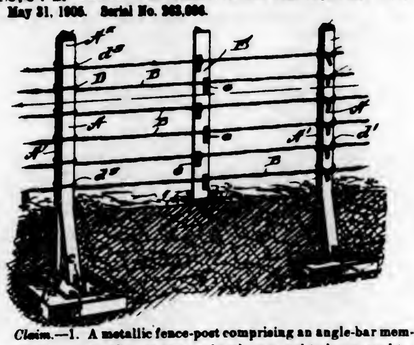
6. In combination, a plow-beam, a frame from which the latter is adjustably suspended, a lever for raising said plow, a bail operatively connected with said lever and beam, a hook loosely connected to said bail, and a lug on the beam adapted to be engaged by said hook upon the operation of said lever.

7. In combination, a plow-beam, a frame from which the latter is adjustably suspended, a plate on the beam having an outwardly-extended lug thereon, a shaft, a bail connected respectively to said shaft and plate, a lever operatively associated with said bail, and a hook operable upon the movement of said lever and bail adapted to engage said lug.

8. In combination a plow-beam, a frame from which said beam is suspended, a shaft on the frame having a serrated bearing-face, a bail operatively connected adjacent its respective ends to said shaft and beam, a lever for adjusting the beam, having a serrated bearing-face adapted to engage the complementary face of the shaft whereby the adjustable connection is formed, and means for retaining the beam in adjustable positions.

9. In combination, a plow-beam and a frame from which the plow-beam is suspended, a lever for raising said plow, a shaft to which said lever is pivoted, a bail connected respectively to the shaft and plow-beam, a second lever operatively connected intermediate its ends to said bail, and having at its lower end a hook, and a lug on the beam adapted to be engaged by said hook.

812,274. **FENCE.** JOHN KEMPF, Jr., Salt Lake City, Utah. Filed May 31, 1905. Serial No. 263,606.



Claim.—1. A metallic fence-post comprising an angle-bar member and a brace member constructed and arranged to be secured together to clamp the longitudinal wires therebetween, the lower portions of said members being separated to form a base for the post.

2. A metallic fence-post comprising an angle-bar member and a brace member constructed and arranged to be secured together to clamp the longitudinal wires therebetween, the lower portions of said members being separated to form a base for the post, and an anchor to which the lower ends of said members are adapted to be connected.

3. A metallic fence-post comprising an anchor-plate, a straight, vertical angle-bar mounted thereon, a brace member mounted on said base at a distance from said angle-bar and bent so that in its upper portion it enters the concavity of said angle-bar to form therewith a clamp for the longitudinal wires and means to secure said members together.

4. A metallic fence-post comprising a straight angle-bar member and a tubular brace member adapted to enter the concavity of said angle-bar member and form therewith a clamp for the longitudinal wires of the fence, said tubular member being bent away from said angle-bar member near its lower end so as to give stability to the post, and means to secure said members together.

5. A metallic fence-post comprising an angle-bar member and a brace member having its upper portion straight and adapted to extend into the concavity of the angle-bar member to form therewith a clamp for the longitudinal wires, and having its lower portion bent outward away from the angle-bar member, and an anchor connecting the lower ends of the two fence-post members.

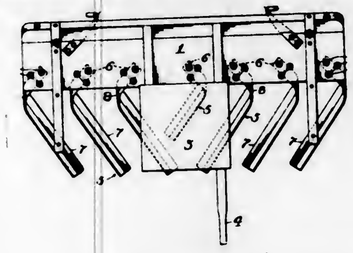
6. A metallic fence-post comprising an angle-bar member and a brace member having its upper portion straight and adapted to extend into the concavity of the angle-bar member to form therewith a clamp for the longitudinal wires, and having its lower portion bent outward away from the angle-bar member, the fence-post members being slotted at their lower ends and an anchor having a horizontal portion and a vertical portion adapted to enter the slots in the fence-post members and secured therein to connect the lower ends of such members.

812,275. **ARTIFICIAL LIMB.** WILLIAM M. KEMPOEL, Duluth, Minn. Filed May 31, 1905. Serial No. 263,197.

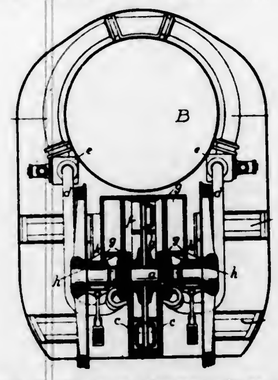
Claim.—In an artificial limb, the combination with a socket portion for the reception of the wearer's limb, of a concentric wall-cushion formed of factice, a composition of a fat oil or oils and sulfur, positioned in said socket, substantially as described.

812,276. **WEED-CUTTER.** JOHN KELLEHER, Los Angeles, Cal. Filed Oct. 10, 1904. Serial No. 227,833.

Claim.—A weed-cutter provided with a cutting-blade having a substantially flat, straight, underground portion extending rearwardly parallel with the surface of the earth, the cutting edge of said underground portion inclined laterally to the direction of draft, a shank for attaching said blade to an implement, and a bent portion connecting the shank to the straight portion, the forward edge of said bent portion being in position to encounter the soil throughout substantially the entire length thereof and lying in the plane of the side of a cylinder parallel with the line of draft.



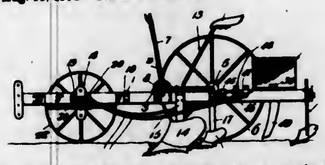
812,277. **TURBINE-DRIVEN LOCOMOTIVE.** HUGO LENTZ, Berlin, Germany. Filed Aug. 16, 1905. Serial No. 274,376.



Claim.—1. In combination, a locomotive-frame, a driving-axle therefor, a turbine-wheel connected with said axle, a turbine-casing, for said wheel, provided with bearing parts which rest upon axle-boxes through which the axle passes.

2. In combination, a locomotive-frame, a driving-axle therefor, a turbine-wheel connected with said axle, a turbine-casing, for said wheel, provided with bearing parts which are connected with axle-boxes through which the axle passes.

812,278. **SEED-PLANTER.** PHILIP LE SUEUR, Los Angeles, Cal. Filed Aug. 11, 1904. Serial No. 220,323.



Claim.—1. In combination with a plow-beam, a pair of plates bolted to the beam and having a series of holes, a pair of bushings in opposite holes, an axle through the bushings, a wheel on the axle, cranks on the axle, knuckle-joints on the axles, pitmen having ends extending into the knuckle-joints, the pitman having a series of holes, and pins through the knuckle-joints and pitmen, a hopper having a central discharge hole, a pair of slides over the hole, and having seed-holes, and detachable connections from the pitmen to the slides.

2. The combination with a dropper-slide, and an operating-axle, carrying a crank, of a knuckle-joint pivotally mounted on said crank and a pitman longitudinally adjustable in said knuckle-joint and connected to said dropper-slide.

3. The combination with a dropper-slide, and an operating-axle carrying a crank, of a knuckle-joint pivotally mounted on said crank and connected to said dropper-slide, said knuckle-joint comprising an eye member, having a hole at right angles to the eye and a cotter-pin through the member, the pitman having a series of holes for receiving the cotter-pin.

4. A seed-planter having a beam comprising bars, dropper-slides between said bars, cross-head guides supported on and extending across said bars and connected with said slides, respectively, and pitmen outside said bars and connected with and supported by said cross-heads, respectively.

5. In a seed-planter, a beam comprising two bars formed with a front loop for receiving the wheel and with a larger rear loop with a pair of bars extending from the neck of the front loop through the center of the rear loop and uniting with the back bar of the rear loop, a hopper on the latter pair of bars, suitable dropping-slides, a wheel within the front loop, cranks for the wheel, and suitable connections from the cranks to the slides, a rear axle on the large loop, wheels on on the axle, and suitable plows carried by the frame.

6. In combination with a plow-beam, a hopper mounted thereon, dropper-slides for the hopper, cross-head guides on opposite sides of the beam in front of the hopper, cross-heads mounted on the respective guides, a gage-wheel and axle, cranks thereon, pitmen connecting the cranks and respective cross-heads, and means for detachably connecting the dropper-slides with the cross-heads.

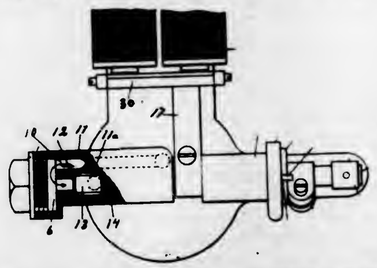
7. In combination with a plow-beam, a hopper mounted thereon, dropper-slides for the hopper, cross-head guides on opposite sides of the beam in front of the hopper, cross-heads mounted on the respective guides, a gage-wheel and axle, cranks thereon, pitmen connecting the cranks and cross-heads, screws threaded into the cross-heads, each dropper-slide having a hole for engaging an end of a screw.

8. In combination with a plow-beam, a hopper mounted thereon, dropper-slides for the hopper, cross-head guides on the beam, cross-heads mounted on the guides, an operating-axle carrying cranks, knuckle-joints pivotally mounted on the cranks, pitmen adjustable in the knuckle-joints, and connected to the cross-heads, and means for detachably connecting the dropper-slides with the cross-heads.

9. In combination with a plow-beam, a hopper mounted thereon, slideways in the hopper-bottom, dropper-slides to slide therein, anticlogging gates pivotally attached to the sides of the slideways at the front and rear end of said hopper, said anticlogging gates exerting a yielding pressure upon the outer ends of the dropper-slides.

10. In combination with a plow-beam, a hopper mounted thereon, slideways in the hopper-bottom, dropper-slides to slide therein, anticlogging gates pivotally attached to the sides of the slideways at the front and rear ends of the hopper, said anticlogging gates provided with means for automatically adjusting themselves to thick and thin dropper-slides.

812,279. **AUTOMATIC ENGINE-STOP.** NATHANIEL C. LOCKE, Salem, Mass., assignor to Locke Regulator Company, Kittery, Me., a Corporation of Maine. Filed Apr. 10, 1905. Serial No. 254,735.



Claim.—1. The combination with a main shut-off valve and its casing, of a coöperating puppet-valve and its casing, an auxiliary valve and its casing, a passage from the inlet end of the puppet-casing extending through the auxiliary-valve casing to the outlet end of the puppet-casing, and means for actuating the auxiliary valve to

control the said passage, whereby the main shut-off valve may be controlled.

2. The combination with a main shut-off valve, a puppet-valve, and an auxiliary valve, casings for each valve, a passage connecting the casings, the puppet-valve being located in said passage between the main and auxiliary valves, and means for actuating said auxiliary valve to control said passage and thus control the shut-off valve.

3. The combination with a main shut-off valve, of a puppet-valve and an auxiliary valve, casings for each valve, a passage controlling said casings, the auxiliary valve being located in the passage so as to control the same, and means for actuating said auxiliary valve by imparting thereto a rotary reciprocating motion.

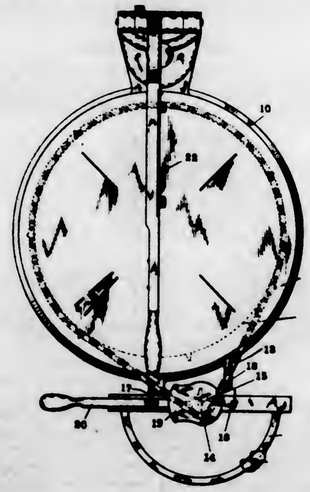
4. The combination with a main shut-off valve, a puppet-valve, an auxiliary valve, casings for said valves, a passage controlling said casings, the auxiliary valve being located in said passage so as to control the same, an electric circuit, in which said auxiliary valve is inserted, and means whereby the closing of said circuit will actuate the auxiliary valve to open said passage and actuate the shut-off valve.

5. The combination with a main shut-off valve and its casing, of a puppet-valve and an auxiliary valve, a casing for the two valves last named independent of the main-valve casing, a passage connecting the seats of the puppet and auxiliary valves, a passage connecting the two casings, and means for actuating the auxiliary valve to control the passage between the same and the puppet-valve and thus control the operation of the main shut-off valve.

6. The combination of a piston connected with a puppet; a casing therefor; an automatic auxiliary-valve casing provided with an exhaust-steam chamber; a passage from the top side of the piston to the outlet end of the puppet-casing; and an automatically-actuated valve controlling said passage, said auxiliary valve being formed on a rockable spindle extension formed with a quick-screw and mounted in a threaded socket in the auxiliary valve casing; a latch fast on said extension; a spring operatively connected with said extension; a movable armature provided with a shoulder to engage said latch; a magnet; and means to hold said armature in engagement with said latch.

7. The combination with a main shut-off valve, of a piston connected with a puppet and casing therefor, a passage controlling the piston-casing with the outlet end of the puppet-casing, and an electrically-actuated auxiliary valve controlling said passage, a casing therefor, said auxiliary valve being formed on a rockable spindle provided with a quick-screw mounted in a threaded bearing in the auxiliary-valve casing; a latch fast on said spindle; a spring operatively connected with said spindle; an armature provided with a shoulder to engage said latch; a magnet; and means to hold said armature in engagement with said latch.

812,280. COMPUTING CHEESE-CUTTER. GEORGE P. LOUISO and CHARLEY H. HENSLEY, Anderson, Ind., assignors of one-third to said Louiso and two-thirds to Jesse L. Vermillion, Anderson, Ind. Filed Apr. 14, 1905. Serial No. 255,640.



Claim.—1. In a cheese-cutter, the combination with the base, of a cheese-carrying table rotatably mounted thereon, an operating-shaft arranged substantially parallel with the axis of the table, a chain-engaging member carried by said shaft, a chain-engaging member carried by the table, an endless chain passing around the said two members, means for keeping said chain tight to prevent independent movement of the table, and an operating member adapted to drive the shaft and chain in one direction only.

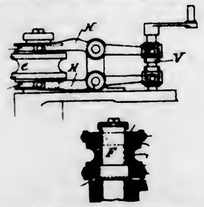
2. In a cheese-cutter, the combination with a base and a knife carried thereby, of a cheese-carrying table rotatably mounted on said base in position to coöperate with said knife, a shaft-carrier movably mounted on said base, an operating-shaft journaled in said carrier, an endless belt passing around said shaft and said table to drive the table, means for adjusting the shaft-carrier so as to vary the distance between the axis of the table and said shaft whereby the belt may be held tight to prevent independent movement of the table, and means for driving said shaft and chain in one direction only.

3. In a cheese-cutter, the combination with a base and a knife carried thereby, of a cheese-carrying table rotatably mounted on said base in position to coöperate with said knife, a shaft-carrier movably mounted on said base, an operating-shaft journaled in said carrier, an endless belt passing around said shaft and said table to drive the table, means for adjusting the shaft-carrier so as to vary the distance between the axis of the table and said shaft whereby the belt may be held tight to prevent independent movement of the table, a single-acting clutch-driving connection adapted to engage said shaft to drive the same in one direction only, and an indicator-bar carried by the shaft-carrier in conjunction with said clutch-driver.

4. In a cheese-cutter, the combination with a base, of a rotatable cheese-carrying table mounted thereon, a shaft-carrier movably mounted on said base, a shaft journaled in said carrier substantially parallel with the axis of the table, an endless belt passing around said table and said shaft, means for driving the shaft, and means for adjusting the shaft-carrier on the base, for the purpose set forth.

5. In a cheese-cutter, the combination with a base, of a rotatable cheese-carrying table mounted thereon, a shaft-carrier movably mounted on said base, a shaft journaled in said carrier substantially parallel with the axis of the table, an endless belt passing around said table and said shaft, means for driving the shaft, means for adjusting the shaft-carrier on the base, an indicator-bar mounted on the shaft-carrier to move therewith and arranged in conjunction with the shaft-operating means to indicate the amount of movement thereof.

812,281. ROLLING-MACHINE. ALFRED MASION, Molenbeek, Belgium, assignor to Société Générale du Laminage Annulaire, Brussels, Belgium. Filed Jan. 5, 1905. Serial No. 239,756.



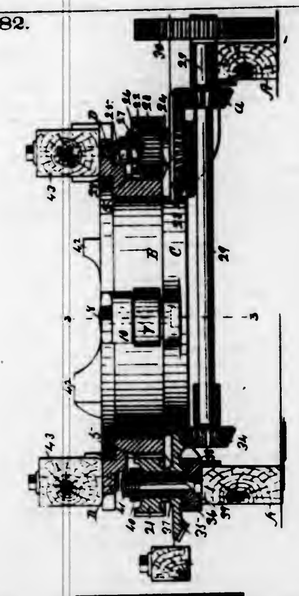
Claim.—1. In a rolling-machine, the combination with a roll, of knives or shears connected with the roll to rotate therewith, and movable toward and from each other in the direction of the axis of the roll, and means for simultaneously adjusting the knives or shears.

2. In a rolling-machine, the combination with a roll, of a circular knife or shear connected with said roll, means for locking the shear to the roll to prevent independent rotation and to permit the shear to be adjusted in the direction of the axis of the roll and means for adjusting the knife or shear.

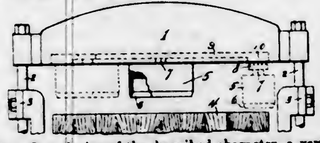
812,282. HORSE-POWER. JOHN G. MOLE, Batavia, Ill. Filed Dec. 30, 1901. Serial No. 87,801.

Claim.—In a horse-power, the combination with a supporting-base provided with a number of vertical bearing-sleeves, of a driving gear-wheel, the friction-rollers loosely mounted on said sleeves, a bolt inserted upward therethrough, a lock-nut threaded on said bolt, a guide bearing-plate, loosely mounted thereon and overlapping a part of said gear-wheel and recessed in the under side to engage the lock-nut and the upper hub end of said rollers, substantially as set forth.

812,282.



812,283. DIE-PRESS. CHARLES L. MCBRIDE, Toledo, Ohio. Filed Mar. 27, 1905. Serial No. 252,268.



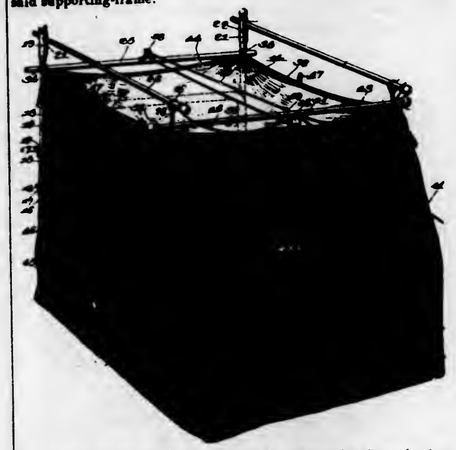
Claim.—In a device of the described character, a vertically-reciprocable horizontal beam having in its face an internally-enlarged longitudinal slot with enlarged openings at each end, combined with a cutting-die, a shank projecting from the middle of the back of the die, and a head on the extremity of the shank adapted to enter said enlarged opening and to engage said longitudinal slot.

812,284. MOSQUITO-NET-FRAME ATTACHMENT FOR BEDSTEADS. WILLIAM K. MCCARDELL, Houston, Tex. Filed June 24, 1905. Serial No. 266,325.

Claim.—1. In a device of the class described, spaced rods swinging from one end and extending longitudinally of a bedstead and above the same, a stretcher-bar slidable upon said rods, and provided with a central guide member, a guy-cord connected at the ends of said rods and slidable through said guy members, a mosquito-net canopy suspended from said bar, and means for moving said bar longitudinally of said rods to cause the same rods to be folded parallel to each other and transversely of said bedstead.

2. In a device of the class described, a supporting-frame having means for attachment to a bedstead, rods spaced apart and mounted to swing from said frame and extending longitudinally of a bedstead and above the same, a stretcher-bar slidable upon said rods and provided with a central guide member, a guy-cord connected at the ends to said rods and passing loosely through said guide member, a guide-pulley connected to said supporting-frame, a pull-cord connected to said stretcher-bar and leading through said guide-pulley and thence through said guide member and a pull-cord connected to said stretcher-bar, and a mosquito-net canopy suspended from said bar.

3. In a device of the class described, a supporting-frame having means for attachment to a bedstead, rods spaced apart and mounted to swing from said frame and extending longitudinally of a bedstead and above the same, a stretcher-bar slidable upon said rods and provided with a central guide member, a guy-cord connected at the ends to said rods and passing loosely through said guide member suspension-cords extending between said supporting-frame and stretcher-bar a mosquito-net canopy connected detachably to said suspension-cords, and means for moving said stretcher toward and away from said supporting-frame.



4. In a device of the class described, a supporting-frame having means for attachment to a bedstead, rods spaced apart and mounted to swing from said frame and extending longitudinally of said bedstead and above the same, a stretcher-bar slidable upon said rods and provided with a central guide member, a guy-cord connected at the ends to said rods and passing loosely through said guide member, suspension-cords extending between said supporting-frame and stretcher-bar, a mosquito-net canopy having spaced loops, means for connecting said loops to said suspension-cords, and means for moving said stretcher-bar toward and away from said supporting-frame.

5. In a device of the class described spaced vertical members located adjacent to the head portion of a bedstead, means for detachably connecting said vertical members to a bedstead, a stay member connected between said rods swinging from said vertical members, a stretcher member slidable upon said rods and provided with a central guide member, a guide-pulley upon said stay member a draw-cord connected to said stretcher-bar and leading through said guide-pulley and thence through said guide member a draw-cord connected to said stretcher member, and a mosquito-net canopy suspended from said stretcher-bar.

6. In a device of the class described spaced vertical members located adjacent to the head portion of a bedstead, and provided with laterally-extending pins, sleeves rotative upon said vertical members and provided with vertical slots having transverse extensions for engaging said pins and limited in their movement thereby, rods rigidly connected to said sleeves and extending laterally therefrom, a mosquito-net canopy suspended from said rods, and means for folding said rods parallel to each other and transversely of said bedstead.

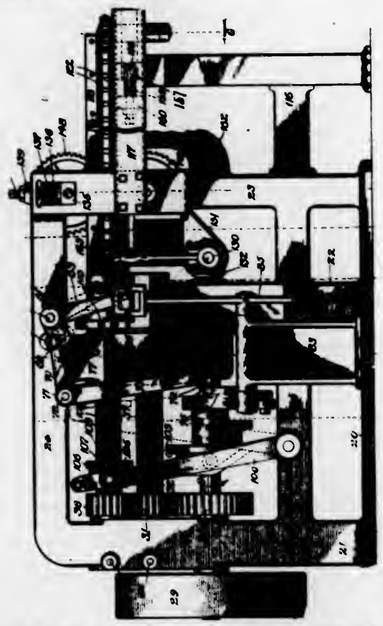
7. In a device of the class described spaced vertical members located adjacent to the head portion of a bedstead, means for detachably connecting said vertical members to a bedstead, a stay member connected between said vertical members, spaced rods swinging from said vertical members, a stretcher member slidable upon said rods and provided with a central guide-pulley upon said stay member a draw-cord connected to said stretcher-bar and leading through said guide-pulley and thence through said guide member a draw-cord connected to said stretcher member, suspension-cords connected between said vertical members and stretcher member, and a mosquito-net canopy provided with spaced loops for detachable connection to said suspension-cords.

812,285. LOCKED-SEAM CAN-BODY MACHINE. JOHN H. MORROY, Chicago, Ill. Filed Apr. 7, 1903. Serial No. 151,838.

Claim.—1. In a device of the class described, the combination with the roller having the seaming-groove therein, of the coöperating roller having the tucking-blade slidingly mounted therein and coöperating with the groove, a stationary member coöperating with the said blade to control the sliding movement thereof as its roller rotates and means for rotating said rollers.

2. In a device of the class described, the combination with the roller having the seaming-groove therein, of the coöperating roller

having the tucking-blade slidingly mounted therein and coöperating with the groove, means within the latter roller for holding the blade immovable relative to the roller carrying it until it has completely entered the groove and then releasing it so that it can be withdrawn, and means for rotating said rollers.



3. In a device of the class described, the combination with the roller having the seaming-groove therein, of the coöperating roller having the tucking-blade slidingly mounted therein and coöperating with the groove, means for holding the blade immovable relative to the roller carrying it until it has completely entered the groove and then releasing it so that it can be withdrawn, means for withdrawing the blade as soon as it is released, and means for rotating said rollers.

4. In a device of the class described, the combination with the roller having the seaming-groove therein, of the coöperating roller having the tucking-blade slidingly mounted therein and coöperating with the groove, means for holding the blade rigid until it has completely entered the groove and then releasing it so that it can be withdrawn, said means consisting of a stationary central portion about which the second roller rotates, said central portion being provided with the cam-recess into which the tucking-blade can drop, and means for rotating said rollers.

5. In a device of the class described, the combination with the roller having the seaming-groove therein, of the coöperating roller having the tucking-blade slidingly mounted therein and coöperating with the groove, a stationary center about which the second roller rotates, said center being provided with the bearing-surface and cam-recess which holds the blade rigid until it has completely entered the groove and then releases it so that it can be withdrawn, a spring interposed between the blade and the second roller to withdraw the blade as soon as the cam-groove is reached, and means for rotating said rollers.

6. In a device of the class described, the combination with the roller having the seaming-groove therein, of the coöperating roller having the tucking-blade slidingly mounted therein at an acute angle to the line connecting the centers of the rollers, a stationary center about which the second roller rotates having the bearing-surface for the tucking-blade and the cam-recess into which it can drop when it has completely entered the seaming-groove, and means for rotating said rollers.

7. In a device of the class described, the combination with the roller having the seaming-groove therein, of the roller coöperating therewith having the tucking-blade engaging the seaming-groove, discharge mechanism coöperating with the first-mentioned roller, means for rotating said rollers, means for holding said rollers firmly in engagement while the can is being formed thereon, and means for releasing them when the can is being discharged.

8. In a device of the class described, the combination with the roller having the seaming-groove therein and making two complete revolutions at each operation, of the second roller coöperating therewith having the tucking-blade engaging the seaming-groove, a discharge mechanism coöperating with the first-mentioned roller, means for rotating said rollers, a movable bearing for said second-mentioned roller, and a cam coöperating with said bearing to hold said rollers firmly together as the can-body is formed thereon, and for releasing them when the can-body is discharged.

9. In a device of the class described, the combination with the roller having the seaming-groove therein, of the stationary center about which said roller rotates, the coöperating roller having the tucking-blade engaging the seaming-groove, a stationary can-support attached to said stationary center, and mechanism for discharging a can-body upon said stationary support.

10. In a device of the class described, the combination with the roller having the seaming-groove therein, of the stationary center about which said roller rotates, the coöperating roller having the tucking-blade engaging the seaming-groove, a stationary can-support attached to said stationary center, mechanism for discharging a can-body upon said stationary support, and means for carrying a can along said support after it has been placed thereon by the discharge mechanism.

11. In a device of the class described, the combination with the roller having the seaming-groove therein, of the stationary center about which said roller rotates, the coöperating roller having the tucking-blade engaging the seaming-groove, a stationary soldering-bar attached to said stationary center, mechanism for discharging a can-body from the first roller onto the soldering-bar, means for carrying the can along said soldering-bar after it has been placed thereon by the discharge mechanism, and supports extending along the soldering-bar and adapted to support the soldering mechanism for soldering the side seam as the can is carried along the bar by said means.

12. In a device of the class described, the combination with the roller having the seaming-groove therein, of the stationary center about which said roller rotates, the coöperating roller having the tucking-blade engaging the seaming-groove, a stationary can-support attached to said stationary center, mechanism for discharging a can-body from the first-mentioned roller upon said stationary support, and mechanism for pressing the seam of the can-body.

13. In a device of the class described, the combination with the roller having the seaming-groove therein, of the stationary center about which said roller rotates, the coöperating roller having the tucking-blade engaging the seaming-groove, a stationary soldering-bar attached to said stationary center, mechanism for discharging a can-body from the first-mentioned roller upon said stationary soldering-bar, means for pressing the seam of the can-body, means for carrying the can along said soldering-bar after it has been placed thereon by the discharge mechanism, and stationary supports along said soldering-bar adapted to support soldering mechanism for soldering the side seam of the can as it is moved along the bar by said means.

14. In a device of the class described, the combination with the roller having the seaming-groove therein, of the stationary center about which said roller rotates, the coöperating roller having the tucking-blade engaging the seaming-groove, a stationary can-support attached to said stationary center, mechanism for discharging a can-body upon said stationary support, and mechanism on said support for pressing the seam of the can-body.

15. In a device of the class described, the combination with the roller having the seaming-groove therein, of the stationary center about which said roller rotates, the coöperating roller having the tucking-blade engaging the seaming-groove, the stationary can-support attached to said stationary center, mechanism for discharging a can-body upon said stationary support, and mechanism on said support for pressing the seam of the can-body consisting of the roller within said support and the pressing-roller coöperating therewith.

16. In a device of the class described, the combination of the two rollers over which the can-body passes and with both of which it engages, with the pressing-roller engaging one of said first-mentioned rollers, a shaft to which it is secured, and a gear-wheel on said shaft, the supporting-roller opposed to the pressing-roller through the two first-mentioned rollers, the shaft upon which it is mounted and the gear-wheel on said shaft meshing with said first-mentioned gear-wheel, means for feeding the can-bodies past said rollers, and means for rotating said gears adapted to carry the can-bodies between the rollers faster than the feeding means moves them.

17. In a device of the class described, the combination of the two rollers over which the can-body passes and with both of which it engages, with the pressing-roller engaging one of said first-mentioned rollers, the supporting-roller opposed to the pressing-roller through the two first-mentioned rollers, and bearings for the three first-mentioned rollers permitting them to move in the line of the axes of the four rollers.

18. In a device of the class described, the combination of the two rollers over which the can-body passes and with both of which it engages, with the pressing-roller engaging one of said rollers, adjustable springs coöperating with the movable bearings for said pressing-roller, and means for feeding the can past said rollers.

19. In a device of the class described, the combination with the body-forming mechanism, of the blank-table from which the blanks are fed one by one to said mechanism, the feeding mechanism for the blanks, and a retarding device comprising a plurality of rollers adapted to be moved into engagement with the top of the blank before it is fed forward.

20. In a device of the class described, the combination with the body-forming mechanism, of the blank-table from which the blanks are fed one by one to said mechanism, the feeding mechanism for the blanks, an edge gage on the blank-table, and a retarding device adapted to be moved diagonally onto the top of the blank to carry its edge into engagement with the edge gage.

21. In a device of the class described, the combination with the body-forming mechanism, of the blank-table from which the blanks are fed one by one to said mechanism, an edge gage thereon, the feeding mechanism for the blanks, and a retarding and positioning device comprising a plurality of rollers adapted to be moved diagonally onto the top of the blank to carry its edge into engagement with the edge gage and to hold it down while operated upon by the feeding mechanism.

22. In a device of the class described, the combination with the body-forming mechanism, of the blank-table from which the blanks are fed one by one to said mechanism, the feeding mechanism for the blanks, a lever carrying a retarding device comprising a plurality of rollers adapted to be moved into engagement with the top of the blank before it is fed forward, and means for adjusting the limit of movement of the lever.

23. In a device of the class described, the combination with the body-forming mechanism, of the blank-table from which the blanks are fed one by one to said mechanism, the feeding mechanism for the blanks, a lever carrying a retarding device comprising a plurality of rollers adapted to be moved into engagement with the top of the blank before it is fed forward, and means for adjusting the limit of movement of the lever consisting of an adjustable pin carried by said lever and a slotted operating-lever coöperating with said pin.

24. In a device of the class described, the combination with the roller having the seaming-groove therein, of the coöperating roller having the tucking-blade engaging the seaming-groove, a blank-table upon which the blank is laid close to said rollers, a reciprocating feeding member engaging the blank, means for giving the feeding member a uniform movement, and an adjustable engaging face on said feeding member.

25. In a device of the class described, the combination with the roller having the seaming-groove therein, of the coöperating roller having the tucking-blade engaging the seaming-groove, a blank-table upon which the blank is laid close to said rollers, a feeding-slide engaging the blank, means for positively giving the slide a uniform movement to feed the blank, an adjustable engaging member on said slide, and a spring for returning said slide to normal position.

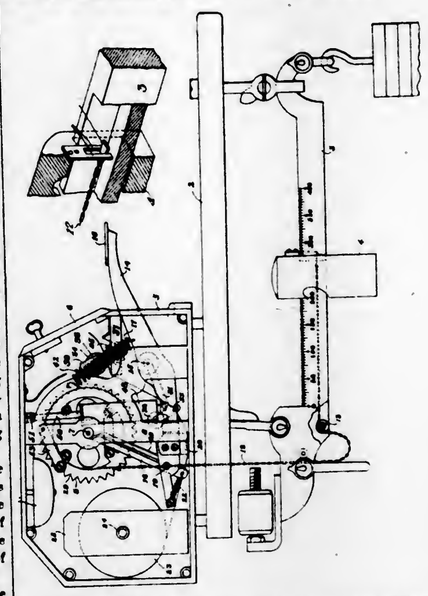
812,286. MECHANICAL RECORDING-SCALE. EDWARD MCGARVEY, Youngstown, Ohio. Filed May 31, 1904. Serial No. 210,513.

Claim.—1. A scale provided with rotatable recording mechanism, a movable poise, a flexible connection between the poise and the recording mechanism adapted to limit its rotation in one direction, with independent means for rotating the recording mechanism to take up the slack in the flexible connection and for pressing a flexible strip against said recording mechanism, substantially as set forth.

2. A scale provided with recording mechanism, a depressible actuating-lever therefor, a movable poise, and a flexible connection between the poise and the recording mechanism, substantially as set forth.

3. A scale provided with rotatable recording mechanism, a frictional actuating device therefor, a movable poise, and a flexible connection between the poise and the recording mechanism adapted to limit its rotation in one direction, substantially as set forth.

4. The combination with a scale-beam provided with an adjustable poise, of a pivoted printing-wheel having peripheral type, a frictional actuating device engaging the printing-wheel, and a connecting-chain attached to the poise and to the printing-wheel adapted to limit its rotation in one direction during subsequent inoperative movement of the actuating device, substantially as set forth.



5. The combination with a scale-beam provided with an adjustable poise, of a pivoted printing-wheel provided with stamping-type on its periphery, means for rotating the wheel, means for limiting its rotation connected with the movable poise and depending upon the position thereof, and means for pressing a recording-surface against the wheel, substantially as set forth.

6. The combination with a scale-beam provided with an adjustable poise, of a pivoted printing-wheel provided with peripheral stamping-type, means for rotating the wheel to bring the type into register, a limiting flexible connection connected with the wheel and with the poise, a recording-strip, means for pressing the strip against the wheel, and means for feeding the strip, substantially as set forth.

7. The combination with a scale-beam provided with an adjustable poise, of a pivoted printing-wheel, a movable poise, and an intervening connection between the poise and wheel by which its rotation is limited, means for rotating the wheel, means for pressing a recording-surface against the wheel, means for positively holding the wheel during the printing operation, and means for feeding the strip, substantially as set forth.

8. The combination with a scale-beam provided with an adjustable poise, of a pivoted printing-wheel, a poise, an intervening connection adapted to limit the movement of the wheel, an inking device, a recording-strip, and a depressible lever provided with means for bringing the strip into contact with the wheel, means for feeding the strip, means for inking the type of the wheel, and a pivoted friction-bar arranged to actuate the wheel, substantially as set forth.

9. The combination with a scale-beam provided with an adjustable poise, of a printing pivoted wheel having peripheral type, actuating mechanism therefor arranged to rotate the printing-wheel, a movable poise connected with the printing-wheel and arranged to limit its rotation dependent on the position of the poise, means for pressing a recording-surface against the type of the wheel, and a signal device, substantially as set forth.

10. The combination with a scale-beam and movable poise thereon, of a rotatable pivoted type-wheel, a flexible connection between the type-wheel and the poise whereby its rotation in one direction is limited, means for pressing a recording-strip against the type-wheel, means for positively actuating the type-wheel, and means for returning it, substantially as set forth.

11. In a recording-scale, the combination with a scale-beam and a movable poise mounted thereon, of a pivoted wheel provided with peripheral type, a flexible connection between the poise and said wheel arranged to limit its rotation in one direction, a pivoted spring-retracted lever provided with a friction-arm arranged to rotate the wheel, means for positively locking the wheel, means for feeding a printing-strip, an inking device, and a pressing-platen incorporated with said lever arranged to press the strip against the type of the wheel, substantially as set forth.

12. The combination with a pivoted type-wheel and a movable check flexibly connected therewith arranged to arrest its rotation, of a pivoted lever provided with a friction-bar arranged to rotate the type-wheel, and a supplemental type-wheel arranged to operate in combination with the first type-wheel, with means for independently adjusting said supplemental wheel dependent on the presence and absence of the scale-weights, substantially as set forth.

13. The combination with a primary pivoted wheel provided with peripheral type, a movable check flexibly connected therewith, a frictional hub, and an actuating-lever provided with a pivoted friction-bar; of a supplemental type-wheel provided with a pinion, a rack-bar in engagement with said pinion provided with an actuating-spring arranged to impart motion to said rack-bar and supplemental type-wheel and a weight-rack adapted to support the weights in alinement with said bar so that upon removal of one or more weights constituting abutments for said rack-bar the bar will become operative, substantially as set forth.

14. The combination with a primary pivoted type-wheel provided with peripheral type, a poise, an intervening flexible connection, and a pivoted lever provided with a friction-bar arranged to actuate the type-wheel; of a supplemental type-wheel provided with a pinion, a spring-actuated rack in engagement therewith arranged to make abutting contact against the scale-weights when in position on the rack, and strip-pressing mechanism, and wheel-locking devices incorporated with the pivoted lever, substantially as set forth.

15. In a scale, the combination of a primary and a secondary type-wheel, a pivoted lever provided with friction-bars arranged to rotate said wheels, strip-pressing mechanism incorporated with said lever, a units-beam provided with a poise, a supplemental beam provided with a poise and connections from said poises to the primary and secondary wheels whereby their rotation is limited according to the position of the poise, substantially as set forth.

16. Mechanism for rotating a type-wheel consisting of the combination therewith of a pinion provided with spider-arms adapted to bear against the wheel, and a rack-bar in engagement with said pinion with means for limiting rotation of the wheel, substantially as set forth.

17. Mechanism for rotating a type-wheel consisting of a pinion provided with spider-arms adapted to bear against the wheel, and a rack-bar in engagement with said pinion, with means for actuating the rack-bar with means for limiting rotation of the wheel, substantially as set forth.

18. In a recording-scale, the combination with a pivoted type-wheel, of a pivoted actuating-lever provided with a pivoted bar having a friction-surface arranged to rotatably engage the hub of the wheel, means for impacting a pressure through said friction-bar upon the hub, and means for limiting the rotation of the wheel in conformity with the reading of the scale-beam, substantially as set forth.

812,287. **TEST-CLAMP.** THEODORE NAGEL, Chicago, Ill., assignor of one-half to Lathrop H. Collins, Chicago, Ill. Filed Dec. 19, 1904. Serial No. 237,457.

Claim.—1. A clamp comprising a suitable holder, a screw tapped into said holder, two clamping-plates each having enlarged openings through which said screw extends whereby they are adapted to be tilted independently of each other and said screw.

2. A clamp comprising a suitable holder, a screw tapped into said holder, two clamping-plates each having enlarged openings through which said screw extends, whereby they are adapted to be tilted independently of each other and said screw and one of said plates having longitudinal grooves in the surface opposed to the other plate.

3. A clamp comprising a suitable rectangular channel-shaped holder, a screw tapped into said holder, and a flat clamping-plate having an enlarged opening therein the edges of which are concentric with said screw through which said screw extends and said plate adapted to be tilted independently of said screw.

4. A clamp comprising a suitable channel-shaped holder, a screw tapped into said holder, two clamping-plates each having enlarged openings through which said screw extends, whereby they are adapted to be tilted independently of each other and said screw.

5. A clamp comprising a suitable channel-shaped holder, a screw tapped into said holder, two clamping-plates each having enlarged openings through which said screw extends, whereby they are adapted to be tilted independently of each other and said screw, and one of said plates having longitudinal grooves in the surface opposed to the other plate.

6. A clamp comprising a suitable rectangular channel-shaped holder, a screw tapped into said holder, and a flat clamping-plate having an enlarged opening therein the edges of which are concentric with said screw through which said screw extends which has its side edges nearest said holder beveled, and said plate adapted to be tilted independently of said screw.

7. A clamp comprising a suitable channel-shaped holder, a screw tapped into said holder, two clamping-plates each having enlarged openings through which said screw extends, whereby they are adapted to be tilted independently of each other, and said screw, the plate engaging the bottom of said holder having its side edges adjacent thereto beveled or undercut.

8. A clamp comprising a suitable channel-shaped holder, a screw tapped into said holder, two clamping-plates each having enlarged openings through which said screw extends, whereby they are adapted to be tilted independently of each other and said screw, one of said plates having longitudinal grooves in the surface opposed to the other plate, and the one engaging the bottom of said holder having its side edges undercut.

9. A clamp comprising a suitable rectangular holder, a screw tapped into said holder, and a flat clamping-plate having an enlarged opening therein the edges of which are concentric with said screw through which said screw extends and with which it has a swiveled engagement and said plate adapted to be tilted independently of said screw.

10. A clamp comprising a suitable holder, a screw tapped into said holder, two clamping-plates each having enlarged openings through which said screw extends, one of said plates having a swiveled engagement with said screw whereby both are adapted to be tilted independently of each other and said screw.

11. A clamp comprising a suitable holder, a screw tapped into said holder, two clamping-plates each having enlarged openings through which said screw extends, one of said plates having a swiveled engagement with said screw whereby both are adapted to be tilted independently of each other and said screw, one of said plates having longitudinal grooves in the surface opposed to the other plate.

12. A clamp comprising a suitable rectangular channel-shaped holder, a screw tapped into said holder, and a flat clamping-plate having an enlarged opening therein the edges of which are concentric with said screw through which said screw extends and with which it has a swiveled engagement, and said plate adapted to be tilted independently of said screw.

13. A clamp comprising a suitable channel-shaped holder, a screw tapped into said holder, two clamping-plates each having enlarged openings through which said screw extends, one of said plates having a swiveled engagement with said screw whereby both are adapted to be tilted independently of each other and said screw.

14. A clamp comprising a suitable channel-shaped holder, a screw tapped into said holder, two clamping-plates each having enlarged openings through which said screw extends, said plates having a swiveled engagement with said screw whereby both are adapted to be tilted independently of each other and said screw.

15. A clamp comprising a suitable rectangular channel-shaped holder, a screw tapped into said holder, and a flat clamping-plate having an enlarged opening therein the edges of which are concentric with said screw through which said screw extends, which has a swiveled engagement with said screw and has its side edges nearest said holder beveled, and said plate adapted to be tilted independently of said screw.

16. A clamp comprising a suitable channel-shaped holder, a screw tapped into said holder, two clamping-plates each having enlarged openings through which said screw extends, one of said plates having a swiveled engagement with said screw whereby both are adapted to be tilted independently of each other and said screw, the plate engaging the bottom of said holder having its side edges adjacent thereto beveled or undercut.

17. A clamp comprising a suitable channel-shaped holder, a screw tapped into said holder, two clamping-plates each having enlarged openings through which said screw extends, one of said plates having a swiveled engagement with said screw whereby both are adapted to be tilted independently of each other and said screw, one of said plates having longitudinal grooves in the surface opposed to the other plate, and the one engaging the bottom of said holder having its side edges undercut.

18. A clamp comprising a suitable rectangular holder, a screw having a convexed bearing-boss adjacent to the head thereof, and a flat clamping-plate having an enlarged opening through which said screw extends the edges of which engaged by said boss are countersunk.

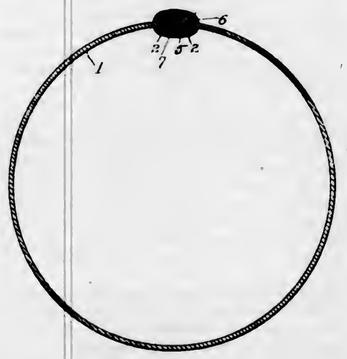
19. A clamp comprising a suitable holder, a screw tapped into said holder and having a bearing-boss adjacent to the head thereof, two clamping-plates each having enlarged openings through which said screw extends whereby they are adapted to be tilted independently of each other and said screw, the plate which is engaged by said boss having a countersunk seat therefor concentric with its opening.

20. A clamp comprising a suitable channel-shaped holder, a screw tapped into said holder and having a bearing-boss adjacent to the head thereof, two clamping-plates each having enlarged openings through which said screw extends, one of said plates having a swiveled engagement with said screw whereby both are adapted to be tilted independently of each other and said screw, one of said plates having longitudinal grooves in the surface opposed to the other plate, and the one engaging the bottom of said holder having its side edges undercut, and the plate which is engaged by said boss having a countersunk seat therefor concentric with its opening.

21. A clamp comprising a suitable channel-shaped holder, a screw having a convexed bearing-boss adjacent to the head thereof, and a clamping-plate having an enlarged opening through which said screw extends the edges of which engaged by said boss are countersunk.

22. A clamp comprising a suitable rectangular channel-shaped holder, a screw tapped into said holder and having a bearing-boss adjacent to the head thereof, two flat clamping-plates each having enlarged openings through which said screw extends whereby they are adapted to be tilted independently of each other and said screw, and the plate which is engaged by said boss having a countersunk seat therefor concentric with its opening.

812,288. **LOCK-SEAM PIPE.** HANS P. G. NORSTRAND, Chicago, Ill. Filed Jan. 24, 1903. Serial No. 140,432.



Claim.—1. A lock-seam pipe, comprising the pipe proper formed of sheet metal and having a longitudinal seam, wires extending longitudinally of the pipe and over which the longitudinal edges of the pipe are turned to form enlarged terminal portions having a shoulder at the base of the turn, and a locking-strip arranged to be bent over and clamped around said enlarged terminal portions, said locking-strip having a shoulder adapted to coöperate with the shoulder on the enlarged terminal portion.

2. A lock-seam pipe comprising the shell or pipe proper formed of sheet metal and having a longitudinal seam, wires over which the longitudinal edges of the pipe are turned, and whose longitudinal axis lies on the neutral axis of the shell, and a locking-strip engaging and holding such edges to lock the joint or seam.

3. A lock-seam pipe having a longitudinal seam and comprising the shell or pipe-body whose longitudinal edges are flat and of a thickness uniform with the shell, wires over which such edges are turned and whose longitudinal axis lies on the neutral axis of the shell, and a locking-strip engaging and holding such edges to lock the joint or seam.

4. A lock-seam pipe having a longitudinal seam and comprising the shell or pipe-body formed of sheet metal, wires over which the longitudinal edges of the pipe are turned to form a shoulder at the base of the turn, and a locking device consisting of an I-shaped strip whose flange portions are bent over the edges of the pipe with their extreme ends abutting the body of the pipe, one of said flange portions forming a shoulder adapted to coöperate with the shoulder at the base of the turn, whereby such flange portions embrace such edges and lock the joint or seam.

5. A lock-seam pipe having a longitudinal seam, and comprising the shell or pipe-body formed of sheet metal, wires over which the longitudinal edges of the pipe are turned to form enlarged terminal portions having a shoulder extending along the base of the turn, and a locking device consisting of an I-shaped strip whose flange portions are bent over the enlarged terminal portions of the pipe, one of said flange portions forming a shoulder adapted to coöperate with the shoulder at the base of the turn, and packing arranged in the inner corners of the locking-strip to seal the joint or seam.

6. A lock-seam pipe, comprising the pipe proper formed of sheet metal and having a longitudinal seam, the edges of said pipe being turned back upon themselves in an open loop to form enlarged and elastic terminal portions, and a locking-strip engaging and holding such enlarged and elastic terminals to lock the joint or seam.

7. A lock-seam pipe, comprising the pipe proper formed of sheet metal and having a longitudinal seam, wires over which the longitudinal edges of the pipe are turned, without being brought into close contact therewith, to form enlarged and elastic terminal portions, and a locking-strip arranged to engage and hold said portions to lock the joint or seam.

8. A lock-seam pipe, comprising the pipe proper formed of sheet metal and having a longitudinal seam, the longitudinal edges of the pipe adjacent to the seam being turned back upon themselves in an open loop to form elastic enlargements, and a locking-strip of substantially I-beam section whose web portion is arranged between the edges of the pipe, and whose top and bottom flanges are pressed upon and substantially surround said elastic enlargements.

9. A lock-seam pipe, comprising the pipe proper formed of sheet metal and having a longitudinal seam, wires over which the longitudinal edges of the pipe are turned to form a substantially cylindrical enlargement whose longitudinal axis lies in the neutral axis of the shell of the pipe, and a locking-strip of substantially I-beam section arranged to engage and hold said edges.

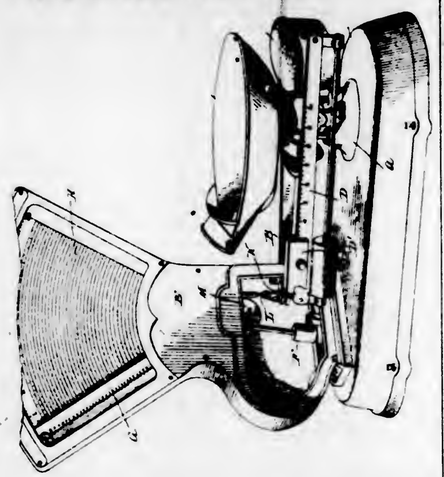
10. A lock-seam pipe, comprising the pipe proper formed of sheet metal and having a longitudinal seam, the longitudinal edges of said pipe being turned back on themselves in an open loop to form elastic enlargements of rounded exterior, a locking-strip of substantially I-beam section arranged to engage and hold such enlarged edges, and packing interposed in the space lying between the rounded exterior of said enlargements and the angular interior surfaces of said I-beam locking-strip.

11. A lock-seam pipe, comprising the pipe proper formed of sheet metal and having a longitudinal seam, wires extending along the edges of the pipe adjacent to said seam and over which the edges of the pipe are turned, without being rigidly secured thereto to form a shoulder at the base of the turn, and a locking-strip arranged to engage and hold said edges, said strip having a portion adapted to coöperate with said shoulder.

12. A lock-seam pipe, comprising the shell proper having a longitudinal seam, wires extending along said seam over which the longitudinal edges of the pipe are turned, but not rigidly secured thereto, the longitudinal axes of said wires lying in the neutral axis of said pipe, and a locking-strip clamped upon said edges to lock the joint or seam.

13. A lock-seam pipe, comprising the pipe-body formed of sheet metal and having a longitudinal seam the edges of said pipe-body being turned back upon themselves in an open loop the base of which projects outside of the plane of the pipe to form a shoulder, said loop forming an enlarged terminal portion, and a locking-strip adapted to embrace the said terminal portions and having a shoulder adapted to coöperate with the shoulder at the base of the turn.

812,289. **PRICE-SCALE.** ORANGE O. OMAR, Dayton, Ohio, assignor to The Computing Scale Company, Dayton, Ohio, a Corporation of Ohio. Filed Oct. 24, 1905. Serial No. 284,256.



Claim.—1. In a price-scale, the combination with the base, the scale-beam pivotally supported on the base and the goods-receiver pivotally supported by the beam, of a price-chart arranged in a vertical plane diagonal to the beam, a connected indicator and pendulum-counterbalance pivoted to move in a plane parallel with the chart and diagonal to the plane in which the beam swings and a connection between the pendulum-counterbalance and beam embodying a needle-point pivot and socket-bearing therefor whereby the length of the leverage is kept uniform in the action of the scale.

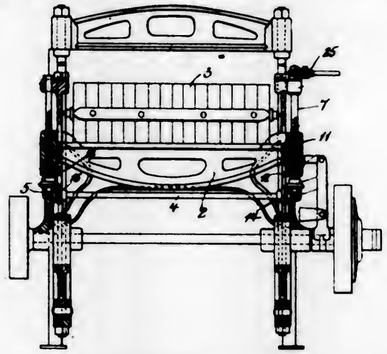
2. In a price-scale, the combination with the base, the beam mounted on transverse pivots to swing in a vertical plane longitudinally of the base and a platform mounted on the beam, of a price-chart arranged in a vertical plane diagonal to the plane in which the beam swings, a combined indicator and pendulum counterbalance pivoted to swing in a plane parallel with and in front of the chart and diagonal to the plane in which the beam swings and a connection between the counterbalance and beam embodying a flexible connector, a yoke and a needle-point pivot on the beam, to prevent variation due to the different planes in which the connected parts move; substantially as described.

3. In a price-scale the combination with the scale-base, the beam pivoted thereon to swing in a vertical plane longitudinally of the base, and a platform supported by the beam, of a vertically-extending housing mounted on the base and having a segmental upper end extending in a vertical plane diagonal to the plane of movement of the beam, a price-chart in the upper part of the housing and exteaded in the plane of the same, a combined indicator and pendulum-weight counterbalance, pivoted in the housing to swing in a plane parallel with the chart and a flexible connection between the beam and counterbalance member embodying a yoke and a single-point pivot whereby changes in leverage due to the different arcs in which the connected members swing is prevented; substantially as described.

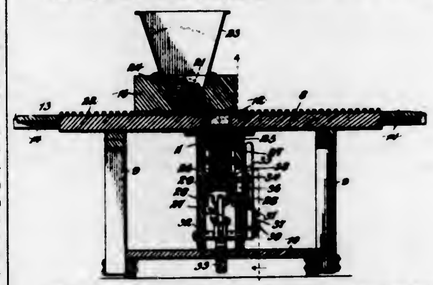
812,290. **BEAM-PRESSER.** HENRY PARSONS, Marlboro, Mass. Filed July 2, 1904. Serial No. 215,144.

Claim.—1. In a machine of the class specified, a vertically-adjusted bed-frame formed with a perforated lug at each end, stationary ways in each side of the framework in which said lugs are arranged, a vertical screw-threaded rod arranged in each lug, bearings for each end of said rods connected to the framework and separate from said lugs or bed, a horizontal rod, a gear upon each end of said rod, a complemeatal gear on the lower end of each vertical rod, a nut on each vertical rod under and supporting one of said lugs and having provisions to prevent turning, and a ratchet for turning one of said vertical rods.

2. In a machine of the class specified, a vertically-adjusted bed-frame formed with a perforated lug at each end, stationary ways in each side of the framework in which said lugs are arranged, a vertical screw-threaded rod arranged in each lug, bearings for each end of said rods connected to the framework and separate from said lugs or bed, a horizontal rod, a gear upon each end of said rod, a complemental gear on the lower end of each vertical rod, one of the gears of said horizontal rod being mounted to be slid out of engagement with its complemental gear, and connections between said rods and said lugs.



812,291. **MOLDING-MACHINE.** LEWIS M. PRATT and ERASTUS H. VAN NATTA, Belleville, Kans.; said Pratt assignor to said Van Natta. Filed May 4, 1905. Serial No. 258,861.



Claim.—1. In a molding-machine, the combination with a mold, of a reciprocatory plunger movable therein, a reciprocatory head against which the plunger detachably bears, an actuating hand-lever fulcrumed beneath the head and having an angularly-disposed link member rigidly carried thereby, another link member pivoted at one end to the said angularly-disposed link member and pivoted at its other end to the head, and independently manually operated means engaging the plunger to move the same away from the head.

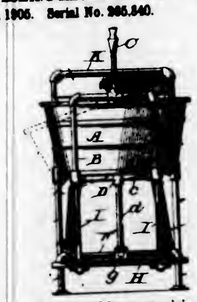
2. In a molding-machine, the combination with a mold, of a reciprocatory plunger movable therein, a reciprocatory head detachably bearing against the plunger, toggle-lever mechanism pivotally connected to the head for moving the same and thereby the plunger, a rod interposed between the head and plunger and bearing against the latter to carry the same away from the head, said rod being detachable from the head, and a lever having a link connection with the rod.

3. In a molding-machine, the combination with a table having a mold therein, of means mounted on the table for feeding material to the mold, a reciprocatory plunger movable in the mold, a reciprocatory head against which the plunger detachably bears, an actuating hand-lever fulcrumed beneath the head and having an angularly-disposed link member rigidly carried at its inner end, the outer end of said lever projecting beyond the table, another link member pivoted at one end to said angularly-disposed link member and pivoted at its other end to the head, another manually-actuated lever fulcrumed beath the table and projecting beyond the same, and means connected to the inner end of the latter lever and associated with the plunger for moving the same away from the head.

4. In a molding-machine, the combination with a mold, of a reciprocatory pressing and ejecting plunger movable therein, spaced

guides located beneath the mold, one of said guides having a slot, a reciprocatory head slidably mounted on the guides and detachably engaging the plunger, toggle-links pivoted to each other and to the head for reciprocating the same, a lever having a fixed connection with the lower set of links for moving the same, a reciprocatory device passing through the slot of the guide and engaging the plunger to carry the same away from the head, and a lever having a link connection with said device.

812,292. **WASHING-MACHINE.** THOMAS C. PURVIS, Chicago, Ill. Filed June 19, 1905. Serial No. 265,840.



Claim.—1. A washing-machine comprising a suitable stand, a rocking frame supported and fulcrumed on the same, a circular tub supported by said rocking frame, a treadle fulcrumed at its center of length and means connecting the ends of the same with said rocking frame.

2. A washing-machine comprising a suitable stand, a normally horizontal spring-returnable rocking frame supported and fulcrumed on the same, a circular tub supported by said rocking frame, a treadle fulcrumed at its center of length and means connecting the ends of the same with said rocking frame.

3. A washing-machine comprising a suitable stand having a longitudinal pivot-bar, a rocking frame supported and fulcrumed on said bar, a circular tub supported and secured on said rocking frame, a treadle fulcrumed mediate its ends in the same vertical plane as said rocking frame and means connecting the end portions of said treadle with the ends of said rocking frame.

4. A washing-machine comprising a suitable stand, a rocking frame supported and fulcrumed on the same, a circular tub supported by said rocking frame, a treadle fulcrumed at its center of length and connecting-rods connecting the ends of the same with said rocking frame.

5. A washing-machine comprising a suitable stand, a normally horizontal spring-returnable rocking frame supported and fulcrumed on the same, a circular tub supported by said rocking frame, a treadle fulcrumed at its center of length and connecting-rods connecting the ends of the same with said rocking frame.

6. A washing-machine comprising a suitable stand having a longitudinal pivot-bar, a rocking frame supported and fulcrumed on said bar, a circular tub supported and secured on said rocking frame, coil-springs connecting the ends of said rocking frame to the base of said stand, a treadle fulcrumed mediate its ends in the same vertical plane as said rocking frame and means connecting the end portions of said treadle with the ends of said rocking frame.

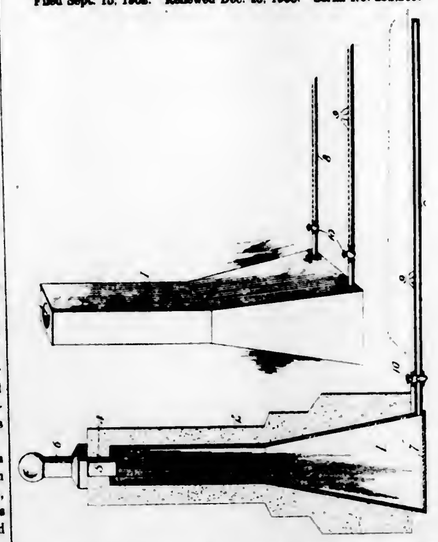
7. A washing-machine comprising a suitable stand having a longitudinal pivot-bar, a rocking frame supported and fulcrumed on said bar, a circular tub supported and secured on said rocking frame, coil-springs connecting the ends of said rocking frame to the base of said stand, a treadle fulcrumed mediate its ends in the same vertical plane as said rocking frame and connecting-rods connecting the end portions of said treadle with the ends of said rocking frame.

8. A washing-machine comprising a suitable stand having a seat for a stationary tub, a longitudinal-pivot-bar alining therewith, a rocking frame supported and fulcrumed on said bar, a circular tub supported and secured on said rocking frame, a treadle fulcrumed mediate its ends in the same vertical plane as said rocking frame, and means operatively connecting the ends of said treadle and rocking frame.

9. A washing-machine comprising a suitable stand having a seat for a stationary tub, a longitudinal pivot-bar alining therewith, a normally horizontal spring-returnable rocking frame supported and fulcrumed on said bar, a circular tub supported and secured on said rocking frame, a treadle fulcrumed mediate its ends in the same vertical plane as said rocking frame, and means operatively connecting the ends of said treadle and rocking frame.

10. A washing-machine comprising a suitable stand having a seat for a stationary tub, a longitudinal pivot-bar alining therewith, a normally horizontal spring-returnable rocking frame supported and fulcrumed on said bar, a circular tub supported and secured on said rocking frame, a treadle fulcrumed mediate its ends in the same vertical plane as said rocking frame, and connecting-rods operatively connecting the ends of said treadle and rocking frame.

812,293. **MONUMENT.** FRITZ G. RANTEAU, Great Falls, Mont. Filed Sept. 15, 1903. Renewed Dec. 13, 1905. Serial No. 292,269.



Claim.—1. A monument, comprising a non-corrosive metallic tank, a covering molded thereabound, a detachable cap forming a closure for the tank, and a valved pipe extending laterally from the bottom of the tank and adapted to be embedded in the ground, that portion of the pipe between its outer end and the valve being perforated.

2. The combination with a monument, consisting of a tank, and a covering molded therearound and simulating stone, of a plurality of parallel pipes extending laterally from the bottom of the tank and adapted to be embedded in the ground, and a valve in each pipe, the tops of the pipes between the valves and the outer ends having series of perforations or outlets therein.

812,294. **WING-NUT.** ALBERT S. REED, Chicago, Ill., assignor of one-half to Elijah T. Harris, Chicago, Ill. Filed May 29, 1905. Serial No. 262,806.

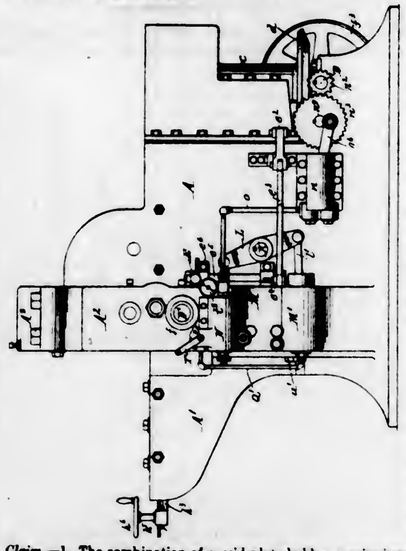
Claim.—1. A wing-nut comprising a shell consisting of a stamped and folded sheet-metal blank, the folded end portions of the blank forming the wings and the central portion of the blank forming the socket, and a nut conforming to the shape of said socket inserted therein.

2. A wing-nut comprising a sheet-metal shell formed with a central socket portion shaped to receive a nut and having its walls extended and folded to form wings, and a separate nut held within said socket.

3. As a new article of manufacture, a winged shell adapted to hold

a nut, said shell consisting of an oblong sheet-metal blank having its end portions folded together along a central line to form wings, and a central portion of said blank struck up to form a socket conforming in shape to a nut

812,295. MACHINE FOR MAKING BATTERY-GRIDS. WILLARD F. RICHARDS, Buffalo, N. Y., assignor to Gould Storage Battery Company, New York, N. Y., a Corporation of West Virginia. Filed Dec. 3, 1901. Serial No. 84,565.



Claim.—1. The combination of a grid-plate holder, a spinning-roll mounted to move toward the grid-plate in said holder, means for reciprocating one of said parts, means for driving said spinning-roll, a fluid-operated device for pressing said spinning-roll yieldingly toward the grid-plate in said holder and the movement of which is opposed by fluid-pressure, a valve controlling the operating fluid for said fluid-operated device, and means for gradually relieving said opposing pressure, whereby only a gradual movement of the spinning-roll toward the grid-plate is allowed regardless of the actuation of said valve, substantially as set forth.

2. The combination of a grid-plate holder, means for reciprocating the same, a spinning-roll mounted to move toward the grid-plate in said holder, means for driving said spinning-roll, a fluid-operated device for pressing said spinning-roll yieldingly toward the grid-plate in said holder, a valve for controlling the operating fluid for said device, and fluid-pressure means for retarding the movement of said device, whereby only a gradual movement of the spinning-roll toward the grid-plate is allowed regardless of the actuation of said valve, substantially as set forth.

3. The combination of a grid-plate holder, means for reciprocating the same, spinning-rolls mounted on opposite sides of said plate-holder to move toward the grid-plate in said holder, means for driving said spinning-rolls, fluid-operated mechanism for pressing said spinning-rolls yieldingly toward the grid-plate in said holder, a valve for admitting the operating fluid to said mechanism, and fluid-pressure means for retarding the movement of said mechanism, whereby only a gradual movement of the spinning-rolls toward the grid-plates is allowed regardless of the actuation of said valve, substantially as set forth.

4. The combination of a grid-plate holder, means for reciprocating the same, spinning-rolls mounted on opposite sides of said plate-holder to move toward the grid-plate in said holder, means for driving said spinning-rolls, a cylinder, a piston in said cylinder and connected to said spinning-rolls, a valve for admitting operating fluid to said cylinder to move said piston and press said spinning-rolls toward the grid-plate, the operative movement of said piston being opposed by fluid-pressure, and means for gradually relieving the pressure opposing the movement of said piston, whereby only a gradual movement of the spinning-rolls toward the grid-plates is allowed regardless of the actuation of said valve, substantially as set forth.

5. The combination of a grid-plate holder, spinning-rolls mounted on opposite sides of said plate-holder and movable toward the latter, means for driving said spinning-rolls, cylinders, fluid-operated pistons in said cylinders, means connecting said pistons to cause them to move oppositely, connections between said pistons and spinning-rolls whereby the latter are moved toward said plate-holder, a valve controlling the admission of operating fluid to said cylinders, and means for controlling the exhaust from said cylinders to cause a gradual movement of said pistons, substantially as set forth.

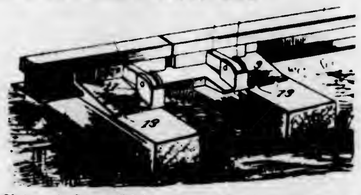
6. The combination of a grid-plate holder, rotary spinning-rolls movable toward and from said plate-holder, cylinders, connected fluid-operated pistons in said cylinders, connections between the same and said spinning-rolls for moving the latter toward the plate, a valve controlling the admission and exhaust of operating fluid to and from said cylinders alternately, and means for causing a gradual exhaust from said cylinders, substantially as set forth.

7. The combination of a reciprocating frame, a grid-plate holder supported by said frame, a bar projecting from one end of said grid-plate holder and constituting a handle therefor, a bracket secured to said reciprocating frame and in which said bar is guided, said bar having rack-teeth on one side and a series of stop-shoulders on another portion, a gear-pinion journaled in said bracket and meshing with said rack-teeth, an operating-handle for said pinion, and a spring-pressed latch mounted on said bracket and held against said bar and adapted to automatically engage with said stop-shoulders to arrest the movement of the grid-plate holder by said pinion, substantially as set forth.

8. The combination of a horizontal grid-plate holder, horizontal spinning-rolls arranged one above and one below said plate-holder, rock-shafts, connections between said rock-shafts and said spinning-rolls for moving the same toward and from each other, and means connecting said rock-shafts whereby the weight of one roll counterbalances that of the other, substantially as set forth.

9. The combination of a horizontal reciprocating grid-plate holder, horizontal spinning-rolls arranged one above and one below said plate-holder, toggles for moving said rolls toward and from each other, horizontal rock-shafts, connections between said rock-shafts and said toggles, and links connecting said rock-shafts whereby said rolls counterbalance each other, substantially as set forth.

812,296. RAIL-JOINT. LEONARD J. ROBICHAUX, NICHOLAS CAILLOUET, and HUBERT F. DELHAYE, Charenton, La. Filed Apr. 3, 1905. Renewed Nov. 24, 1905. Serial No. 288,902.



Claim.—1. In a rail-joint, the combination of the rails provided with holes, a chair having registering holes, a locking-plate having lugs projecting therefrom to pass through the registering holes of the chair and rails, and a locking-dog for holding said locking-plate in position.

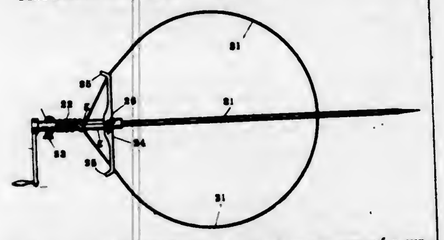
2. In a rail-joint, the combination of the rails provided with holes, a chair having registering holes, a locking-plate having lugs projecting therefrom to pass through the registering holes of the chair and rails, a locking-dog for holding said locking-plate in position, and a spring for holding said locking-dog against accidental displacement.

3. In a rail-joint, the combination of the rails provided with holes, a chair having registering holes, a locking-plate having lugs projecting therefrom to pass through the registering holes of the chair and rails, spaced lugs projecting from the base of said chair, and a dog pivoted to said spaced lugs and adapted to hold said locking-plate in position.

4. In a rail-joint, the combination of the rails provided with holes, a chair having registering holes, a locking-plate having lugs projecting therefrom to pass through the registering holes of the chair and rails, spaced lugs projecting from the base of said chair, a dog pivoted to said spaced lugs and adapted to hold said locking-plate in position, and a spring for holding said dog against accidental displacement when in its normal position.

5. In a rail-joint, the combination of the rails provided with holes, a chair having registering holes, a locking-plate having lugs projecting therefrom to pass through the registering holes of the rails and chair, spaced lugs projecting from the base of said chair, a dog pivoted to said spaced lugs and adapted to hold said locking-plate in position, a metallic spring between said spaced members, and an eccentric portion on said pivoted member adapted to engage with said spring.

812,297. SHOCK-COMPRESSOR. JOHN M. SCHEBLER, Hamburg, Ind., assignor of one-half to George M. Schebler, Indianapolis, Ind. Filed Nov. 16, 1904. Serial No. 233,977.



Claim.—1. The combination, in a shock-compressor, of a support, a winding-drum carried thereby, a head sleeved on said winding-drum and longitudinally movable thereon, a pawl-and-ratchet connection between the head and drum, and a rope, the ends whereof are arranged to be secured to the outer end of said winding-drum in use, whereby as said winding-drum is revolved the said rope is wound up at both ends and held in wound-up condition by the ratchet and pawl, the head carrying said pawl being held in position by forcible contact with the shock being compressed.

2. The combination, in a shock-compressor, of a support, a winding-drum carried by said support, and provided with ratchet grooves or teeth extending longitudinally thereof, a head mounted on said winding-drum and containing a pawl adapted to engage with said grooves or teeth and to travel longitudinally of said winding-drum as the winding operation proceeds, and a rope the ends whereof are secured to said winding-drum.

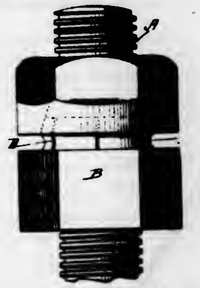
812,298. SILO. DAVID A. SCHLICHTER, Brown City, Mich. Filed Dec. 31, 1904. Serial No. 239,266.

Claim.—1. The combination with a silo provided with a series of doors, of a ladder for said silo, the ladder comprising a series of levers pivotally secured intermediate their ends to the doors, each door carrying at least two levers, the handles of which normally lie in alinement with and project toward each other, the adjacent ends of the levers nearly engaging one another, the opposite ends of the levers being convexed, and catches for the levers, said catches stationarily mounted on the walls of the silo adjacent the levers, opposing concave faces on each catch inclined away from the wall of the silo and terminating at their upper ends in a shoulder to prevent the levers from passing beyond the horizontal in one direction, the convex ends of the levers engaging the concave faces of the catches, whereby the rounds of the ladder are removably locked in position and also serve to hold the doors in place, the rounds being secured more firmly by the ascent or descent thereof.

2. The combination in a silo having an opening therein and doors for closing the opening, of a pair of oppositely-located levers pivotally mounted on each door and catches carried by the silo and engaged by the outer ends of the levers, the inner ends of the levers when in locked position projecting horizontally toward each other to form the rounds of a ladder, the levers being locked by the ascent of a person.

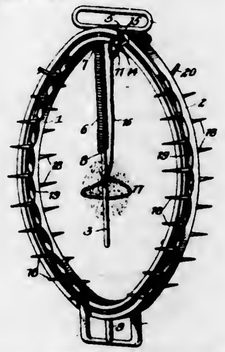
3. The combination in a silo having an opening therein and doors for closing the opening, of a pair of oppositely-located levers pivotally mounted on each door and catches carried by the silo and engaged by the outer ends of the levers, the inner ends of the levers when in locked position projecting horizontally toward each other to form the rounds of a ladder, means on the catches engaged by the outer ends of the levers to prevent the inner ends from moving downward out of horizontal position, the levers being locked by the ascent of a person.

812,299. NUT-LOCK. JOHN SCHMITT, Brooklyn, N. Y. Filed July 5, 1904. Serial No. 215,318.



Claim.—A nut-lock, comprising a working nut, provided with an annular boss, upon one face, said boss being provided with threads having square biting edges, said boss being radially slotted and beveled and flared outwardly, in combination with a lock-nut having a conical-shaped recess in its lower face, the lower edges of the inclined walls of which are cut away, said recess adapted to engage the beveled face of the annular boss, for the purpose of wedging the biting edges of the boss, into the threads of the bolt.

812,300. FISH-TRAP. ARMAND L. SCHUPBACH, New Britain, Conn. Filed Apr. 15, 1905. Serial No. 255,811.



Claim.—1. A trap of the class described, comprising a pair of spring-actuated frames forming jaws, a pivot connecting the frames and extending into the same to form a bait-holder, and means for holding the trap set and for tripping the same.

2. A trap of the class described, comprising a pair of frames forming coöperating jaws, a pivot connecting the frames and extending into the same to form a bait-holder, a spring also mounted on the pivot for actuating the jaws, and means for holding the trap set and for tripping the same.

3. A trap of the class described, comprising a pair of open frames, pivots connecting the frames at diametrically opposite points and provided with handles, one of the handles being connected with one of the frames, and the other handle being connected with the other frame, and means for holding the trap set and for tripping the same.

4. A trap of the class described, comprising a pair of open frames, pivots connecting the frames at diametrically opposite points and provided with handles arranged exteriorly of the frames and consisting of loops, one of the loops being rigid with one of the frames and adapted to be connected to a line and the other loop being rigid with the other frame, and means for holding the trap set and for tripping the same.

5. A trap of the class described, comprising a pair of open frames forming coöperating jaws, a pivot piercing the frames and having an exterior laterally-projecting loop forming a handle and adapted to receive a line, and means for holding the trap set and for tripping the same.

6. A trap of the class described, comprising a pair of open frames, a pivot connecting the frames and extending into the same to provide a bait-holder and exteriorly of the same to form a loop-shaped handle, a spring disposed on the inner portion of the pivot for actuating the jaws, and means for holding the trap set and for tripping the same.

7. A trap of the class described, comprising a pair of open spring-actuated frames pivotally connected and provided with spurs projecting from the engaging edges of the frames, and means for preventing the spurs from coming in contact with the frames when the trap is sprung.

8. A trap of the class described, comprising a pair of open spring-actuated frames pivotally connected and provided at their engaging edges with projecting spurs, and a stop extending from one frame and arranged to be engaged by the other to limit the closing movement of the trap.

9. A trap of the class described, comprising a pair of open spring-actuated frames pivotally connected and having beveled engaging edges, spurs or teeth projecting from the engaging edges, and means for limiting the closing movement of the trap to prevent the spurs or teeth of one of the frames from coming in contact with the other frame.

10. A trap of the class described, comprising a pair of open pivotally-connected spring-actuated frames, and a catch arranged when the frames are opened to their set position to automatically lock the same in such position, and means for holding a bait and for connecting the latter with the catch.

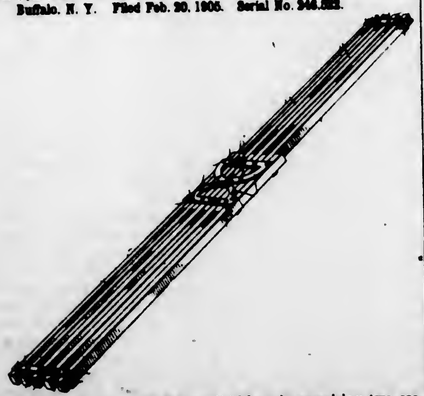
11. A trap of the class described, comprising a pair of pivoted spring-actuated frames, and a catch mounted on one of the frames and having an engaging portion located in the path of the other frame and arranged to be directly engaged by the same when the frames are opened to their set position whereby the frames are automatically locked in such position.

12. A trap of the class described, comprising a pair of pivoted spring-actuated frames, a bait-holder located within the frames, a catch mounted on one frame and arranged to automatically engage the other and to be disengaged therefrom by an inward pull, and means for connecting the catch with a bait.

13. A trap of the class described, comprising inner and outer spring-actuated frames pivoted together, a substantially U-shaped catch secured at one side to the inner face of the inner frame and having its other side located exteriorly of the said inner frame and arranged in the path of the outer frame and provided with means for engaging the same, and means for connecting the catch with a bait.

14. A trap of the class described, comprising a pair of open frames, and a pivot connecting the frames and extending into the same to provide a bait-holder and exteriorly of the same to form a loop-shaped handle.

812,301. **EXTENSIBLE SCAFFOLD-BOARD.** CHARLES SCHWEDT, Buffalo, N. Y. Filed Feb. 20, 1905. Serial No. 246,523.



Claim.—1. An extensible scaffold-board comprising two sections formed of intermeshing strips, the strips of each section being suitably connected at their outer ends and having straps connecting their inner or intermeshed ends, saids straps being arranged on opposite sides of the board and having bolts securing opposite straps to said strips, the straps on one side of the intermeshed ends of the sections comprising a straight portion disposed transversely and a curved portion connected to said straight portion.

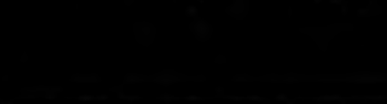
2. An extensible scaffold-board comprising two sections formed of intermeshing strips, the strips of each section being suitably connected at their outer ends and having straps connecting their inner or intermeshed ends, said straps comprising each a straight portion and a curved portion.

3. In an extensible scaffold-board having two sections formed of intermeshing strips, a strap connecting said strips and comprising a straight portion and a curved portion having its ends connected to said straight portion.

4. An extensible scaffold-board comprising two sections formed of parallel intermeshing strips, the strips of each section being connected by straps arranged in pairs, the straps of each pair being on opposite sides of the board and having securing-bolts passing through the latter and said straps, and washers between one of the straps of each pair and the strips forming the sections, said washers surrounding said securing-bolts.

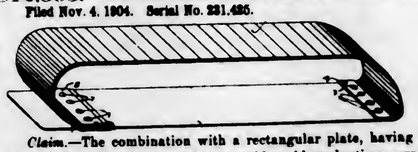
5. An extensible scaffold-board comprising two sections formed of intermeshing strips, the strips of each section being suitably connected at their outer ends and having straps connecting their inner or intermeshed ends, said straps being arranged on opposite sides of the board and having bolts securing opposite straps to said strips, the strap on the under side of each section comprising a straight portion disposed transversely and a curved portion connecting the ends of said straight portion.

812,302. **CAR-REPLACER.** JOHN M. SCUDDER, Farmington, Ill. Filed Nov. 2, 1905. Serial No. 285,606.



Claim.—A car-replacer, comprising a hollow metallic member, having a central longitudinal portion which has double-beveled surfaces, a hollow conical-shaped projection at one end of said double-beveled portion, a headed bolt passing through an aperture in the apex of said conical-shaped projection, a chain secured to said bolt, the opposite end of the member having an aperture in the end thereof, and an anchorage-chain secured thereto, and wings upon said member with their upper surfaces inclined, as set forth.

812,303. **FOOT-MEASURE.** CHARLES SHIVERICK, Omaha, Nebr. Filed Nov. 4, 1904. Serial No. 231,435.

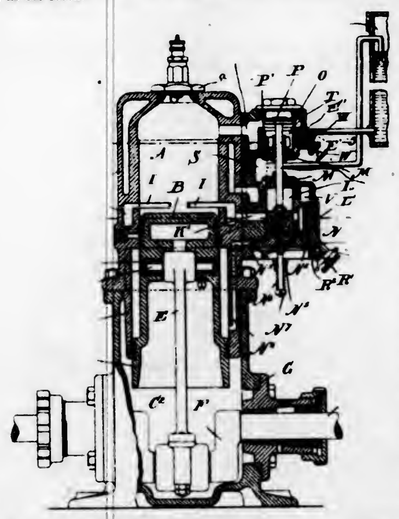


Claim.—The combination with a rectangular plate, having a plurality of scale-graduations upon one side, said graduations corresponding to the length, and width of a human foot, of a flexible holder extending from said plate at one end, and a collar slidably held upon said plate, said flexible member being secured to said collar.

812,304. **EXPLOSIVE-GAS ENGINE.** EDWARD G. SHORTT, Carthage, N. Y. Filed Sept. 24, 1903. Serial No. 174,703.

Claim.—1. An explosive-gas engine having a cylinder with a combustion-chamber and a piston working therein, an exhaust-chamber, a fuel-duct, an air and fuel combining chamber, having free and unobstructed communication with said combustion-chamber, an air-compression compartment, and a vacuum-space intermediate the combustion-chamber and the compression-compartment, a valved passage-way leading from the vacuum-space to said exhaust-chamber, valve mechanism for allowing air under pressure from said compression-compartment together with fuel, to simultaneously enter the combining-chamber, and means for actuating said mechanism exposed on one side to the atmosphere and on the other side to the vacuum-space, as set forth.

2. An explosive-gas engine having a cylinder with a combustion-chamber and a piston working therein, an exhaust-chamber, a fuel-duct, an air and fuel combining chamber, having free and unobstructed communications with said combustion-chamber, an air-compression compartment, and a vacuum-space intermediate the combustion-chamber and the compression-compartment, a valved passage-way leading from the vacuum-space to said exhaust-chamber, valve mechanism for allowing air under pressure from said compression-compartment together with fuel, to simultaneously enter the combining-chamber, a pneumatic cylinder positioned in a passage-way communicating with said vacuum-space, a piston in said pneumatic cylinder and adapted to actuate said valve mechanism, and means for regulating the supply of air to said pneumatic cylinder, as set forth.



3. An explosive-gas engine having a cylinder with a combustion-chamber and a piston working therein, an exhaust-chamber, with ports leading thereto from the lower portion of the combustion-chamber, a fuel-duct, an air and fuel combining chamber, having free and unobstructed communication with the combustion-chamber, an air-compression compartment, the lower end of said piston being enlarged and adapted to form, with the adjacent wall of the cylinder in which it works, a vacuum-space, which communicates through a valve-regulated passage-way with said exhaust-chamber, valve mechanism for allowing the air under pressure from said compression-compartment and fuel to simultaneously enter the combining-chamber, and means for actuating said mechanism exposed on the one side to the atmosphere and on the other side to the vacuum-space, as set forth.

4. An explosive-gas engine having a cylinder with a combustion-chamber and a piston working therein, an exhaust-chamber, a fuel-duct, an air and fuel combining chamber, having free and unobstructed communication with said combustion-chamber, an air-compression compartment, a vacuum-space being formed intermediate the combustion-chamber and the compression-compartment, a pneumatic cylinder with a duct leading therefrom and communicating with said vacuum-space, and valve mechanism for regulating the supply of air from the compression-compartment and fuel to the combining-chamber, simultaneously with the closing of the exhaust to the atmosphere, as set forth.

5. In an explosive-gas engine, a combustion-chamber, an air-compression compartment, a piston working in said chamber and having an enlarged end to compress air into said compartment, a vacuum-space being formed intermediate the circumference of said piston and the wall of the compression-compartment, a combining-chamber, having free communication with the combustion-chamber, an exhaust-chamber with ports leading to the combustion-chamber and to the atmosphere, an induction-valve controlling the feeding of air and fuel to the combining-chamber, a stem upon which said valve is mounted, a pneumatic cylinder, a piston mounted in said cylinder and exposed on one side to the atmosphere and on the other side to the vacuum-space, said piston having a contracted portion for controlling the port leading from the exhaust-chamber, as set forth.

6. In an explosive-gas engine, a combustion-chamber, an air-compression compartment and a vacuum-space, a piston working in said chamber, and having an enlarged end adapted to compress air within said compartment, an exhaust-chamber of measured capacity communicating with the combustion-chamber and with the atmosphere, a combining-chamber communicating with the combustion-chamber, a duct leading from said air-compression compartment to convey air from the latter to the combining-chamber, a pneumatic cylinder and piston working therein, a duct leading from said cylinder to said vacuum-space, an induction-valve and stem secured thereto, which is also fastened to said piston in said cylinder, and valve mechanism in connection with said piston in the cylinder, and means for actuating said mechanism exposed on the one side to the atmosphere and on the other side to the vacuum-space, and means for allowing a given quantity of air to enter the pneumatic cylinder to break the vacuum, as set forth.

7. In an explosive-gas engine, a combustion-chamber, an air-compression compartment and a vacuum-space, a piston working in said chamber, and having an enlarged end adapted to compress air within said compartment, an exhaust-chamber of measured capacity communicating with the lower portion of the chamber and with the atmosphere, an induction-valve for regulating the supply of air and fuel to the combustion-chamber, a pneumatic cylinder, a piston having an enlarged head working in said cylinder and provided with a contracted portion regulating the exit passage-way between said exhaust-chamber and the atmosphere, a valve regulating the ingress of air to said cylinder, said induction-valve actuated by said piston in said cylinder, the latter having communication with said vacuum-space, as set forth.

8. An explosive-gas engine comprising a combustion-chamber, a working piston therein, an annular chamber for receiving the residue of the products of combustion, an induction-valve, a pneumatic cylinder, a piston working therein, having a contracted portion regulating the exit passage-way from said annular chamber to the atmosphere, a valve-regulated air-inlet duct leading to the pneumatic cylinder, a stem on which the piston of said cylinder is mounted, an induction-valve mounted on said stem, and opening into a combining-chamber, a shell in which an enlarged portion of the working piston travels forming a vacuum-space, a port leading from said space to the pneumatic cylinder, an air-compression chamber, a crank-shaft mounted therein, and a pitman between said working piston and shaft, and a duct formed in the casing of the engine and leading from the air-compression chamber to said induction-valve, whereby air under pressure may be fed to the combining-chamber as the induction-valve is unseated, as set forth.

9. An explosive-gas engine comprising a combustion-chamber, a working piston mounted therein, a shell extending below the combustion-chamber, an enlarged portion of said piston working therein, an air-compression compartment, an annular chamber for receiving the residue of the products of combustion, a pneumatic cylinder, a piston having an enlarged headed portion working in said cylinder and a contracted portion regulating communication between the exhaust-chamber and the atmosphere, a stem fitted to said piston in said cylinder, and an induction-valve secured to said stem and regulating the flow of air and fuel to the combining-chamber, as set forth.

10. An explosive-gas engine having a combustion-chamber, a receiving-chamber communicating therewith into which the residue of the products of combustion is forced, a working piston mounted in the combustion-chamber, a shell below the combustion-chamber, forming a space in which an enlarged portion of the working piston reciprocates, an air-compression compartment, a mixing-chamber into which air is conducted from said air-compression compartment, an induction-valve and stem on which the same is mounted, a pneumatic cylinder, a passage-way leading therefrom to said space, a portion of the piston in said cylinder controlling communication between the receiving-chamber and the atmosphere, a guide-piece through which said stem passes, and a spring for normally holding the induction-valve closed, as set forth.

11. In an explosive-gas engine, a combustion-chamber and an air-compression compartment, a piston in said chamber, a receiving-chamber communicating with the combustion-chamber and into which the residue of the products of combustion is forced, an induction-valve, a stem on which the same is mounted, a shell extending below the combustion-chamber, an enlarged portion of said piston working within said shell, a vacuum-space formed between the enlarged portion of said piston and shell, a pneumatic cylinder, a duct leading therefrom to said vacuum-space, a piston mounted in said cylinder and connected to the induction-valve, and a valve-regulated

air-inlet duct leading to said cylinder, a duct leading from the air-compression chamber to the combining-chamber, a valve-regulated

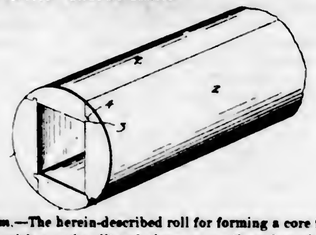
2. A submarine boat, having an optical instrument for receiving and deflecting an image down to the eyepiece of the instrument

which the catch aforesaid is adapted to pass, a shaft mounted on the

2. As an improved article of manufacture, a steel or malleable

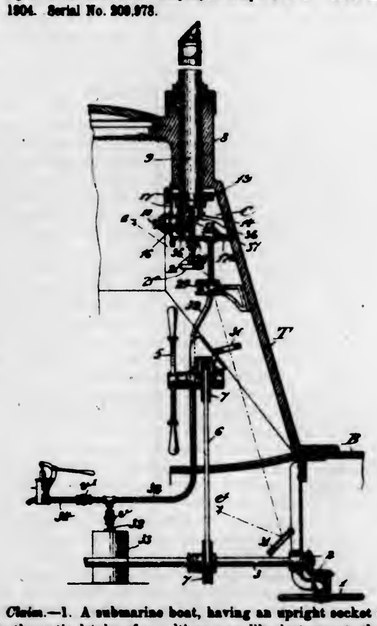
air-inlet duct leading to said cylinder, a duct leading from the air-compression chamber to the combining-chamber, a valve-regulated fuel-aperture opening to the seat of the induction-valve, and a spring-actuated valve regulating the passage-way between said air-compression chamber and said receiving-chamber, as set forth.

812,305. CORE FOR PAPER-ROLLS. SALMA H. SMART, Grand Rapids, Wis., assignor to Earl B. Smart, Grand Rapids, Wis. Filed June 15, 1905. Serial No. 265,263.



Claim.—The herein-described roll for forming a core for paper-rolls comprising a plurality of pieces or sections 2, each provided with a longitudinal tongue on one edge and a corresponding longitudinal groove on one side, said pieces being locked together to form a roll of circular cross-section, and said roll having a rectangular opening extending longitudinally therethrough, substantially as described.

812,306. MEANS FOR STEERING SUBMARINE AND SUBMERGIBLE BOATS. LAWRENCE Y. SPEAR, Greenport, N. Y., assignor to Electric Boat Company, Greenport, N. Y. Filed May 26, 1904. Serial No. 209,978.

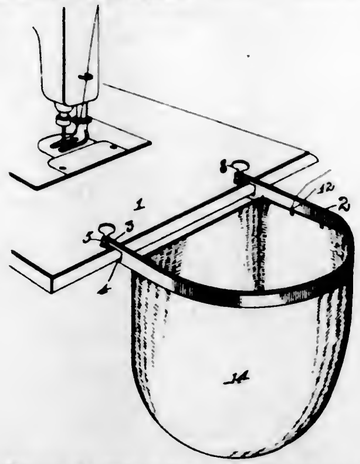


Claim.—1. A submarine boat, having an upright socket to receive the optical tube of an altiscope or like instrument, the said tube, open at its lower end and carrying at its upper end a deflecting-reflector to receive the image, a chamber within the boat below said socket, a hollow support 14 in said chamber, said support having a nook 15 which enters the lower end of the optical tube, a deflecting-reflector 13 in said support, an eyepiece-socket 16 extending through the wall of the said chamber and connected with said wall and with the support 14, the glass 18 in the inner end of the socket 16, the eyepiece mounted slidably in said socket 16, means for rotating the optical tube, a visual indicator actuated by the rotation of said tube to indicate the extent of its rotation, and a telltale-compass 29 situated adjacent to the said eyepiece.

2. A submarine boat, having an optical instrument for receiving and deflecting an image down to the eyepiece of the instrument within the boat for observation, means for rotating axially the optical tube of said instrument, a visual indicator operated by said tube and adjacent to the said eyepiece, to denote the degree of rotation of the tube, a telltale-compass below and adjacent to the eyepiece, a magnifying-lens below said compass, and a reflector below said lens to reflect the readings of the compass to the steersman below.

3. A submarine boat having a steering-wheel and mechanism for a steersman, or helmsman, an auxiliary steering-wheel above the level of the latter for the observer, connecting mechanism whereby the boat may be steered by said auxiliary wheel, a telltale-compass within the range of vision of the observer, and a magnifying-lens and reflector, the latter being so disposed as to reflect the readings of said compass within the range of vision of the steersman below.

812,307. BAG-HOLDER. GEORGE STEARNS, Chicago, Ill. Filed Jan. 3, 1905. Serial No. 239,329.



Claim.—1. In a device of the character described, a strip of resilient material, suitably-spaced parallel longitudinally-disposed arms projecting from each end of the strip, the free portions of the arms being enlarged, set-screws passing through the enlarged portions of certain of the arms to act in conjunction with the enlarged portions of the remainder of the arms to form clamps, and removable contact-pieces carried by the set-screws.

2. In a device of the character described, a strip of resilient material, suitably-spaced parallel longitudinally-disposed arms projecting from each end of the strip, the free portions of the arms being enlarged, set-screws passing through the enlarged portions of certain of the arms to act in conjunction with the enlarged portions of the remainder of the arms to form clamps and yieldable contact-pieces removably carried by the set-screws.

812,308. BOX-FASTENER. HENRY STOTZ, Albert Lea, Minn. Filed June 7, 1905. Serial No. 264,191.

Claim.—1. In a fastening for receptacles, the combination of a catch-plate, an arm extending from the catch-plate, a lug projected from the catch-plate, a catch extending from the arm aforesaid, a shaft mounted in the arm and lug of the catch-plate, and an engaging member projected from the shaft for cooperation with the catch.

2. In a fastening for receptacles, the combination of a receptacle, a strip at the front portion of the receptacle, a catch-plate secured to the front of the receptacle, a catch projected from said catch-plate, a cover for the receptacle provided with a slot through which the catch aforesaid is adapted to pass, a shaft mounted on the catch-plate and passing through the strip aforesaid, and an engaging

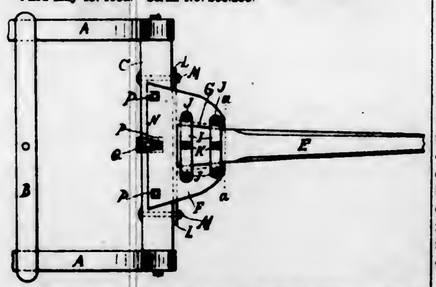
which the catch aforesaid is adapted to pass, a shaft mounted on the catch-plate and passing through the strip aforesaid, and an engaging member carried by said shaft for cooperation with the catch, as specified.

3. In a fastener for receptacles, the combination of a case or box, a cover therefor, a catch-plate applied to the box, a catch projecting from said plate and coacting with the cover, a shaft journaled in the catch-plate, and an engaging member projecting from the shaft and arranged to cooperate with the catch to hold the cover closed.

812,309. BROOM-HANDLE. THOMAS I. SWAGERTY, Pleasanton, Kans. Filed June 9, 1905. Serial No. 264,468.

Claim.—As a new article of manufacture a broom comprising a handle provided at its lower end with a threaded projecting pin and with a casing flared outwardly and projecting beyond the end of the said pin, and a brush portion having at its upper end a shank formed with a longitudinally-extending recess and a keeper embedded in said shank and extending transversely across said recess and provided with a threaded aperture in line with the recess and designed for threaded engagement with the pin, the flared casing providing a guiding means for the reception of the said shank and a proper entry thereinto of the projecting pin, as and for the purpose set forth.

812,310. LOGGING-SLED. ANDREW SWANSON, St. Francis, Minn. Filed May 13, 1905. Serial No. 260,206.



Claim.—1. As an improved article of manufacture, a steel or malleable casting having the horizontal flanges N with bolt-holes adapting said flanges to be bolted to the upper and lower side of the roller of a logging-sled, the vertical side flanges L securable to the front side of the roller, the tapering socket G for the pole, the integral bottom H and the straps I to keep the pole in the socket, and bolts applied substantially as and for the purpose set forth.

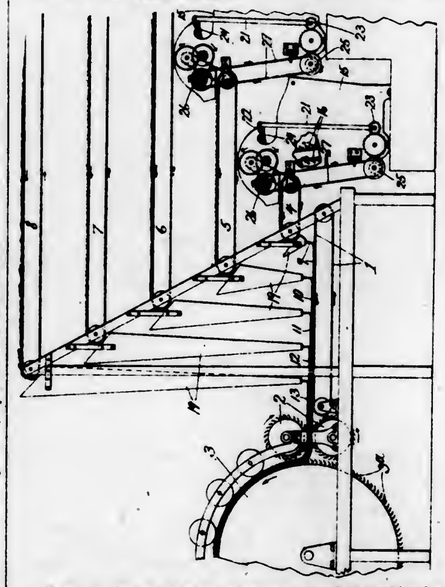
2. As an improved article of manufacture, a steel or malleable casting having the horizontal flanges N with bolt-holes adapting said flanges to be bolted to the upper and lower side of the roller of a logging-sled, the vertical side flanges L securable to the front side of the roller, the tapering socket G for the pole, the integral bottom H and the straps I to keep the pole in the socket, the reinforcing side ribs S, and bolts applied substantially as shown and described.

3. The combination with the pole and roller of a logging-sled, of a casting having a tapering socket or pocket open at the top and front, and the flanges L and N securable to three sides of the roller, and bolts therethrough, said pole having its rear end tapered to fit in the socket and straps bolted to the casting across the pole.

4. The combination with the pole and roller of a logging-sled, of a casting having a tapering socket or pocket open at the top and front, and the flanges L and N securable to three sides of the roller, and bolts therethrough, said pole having its rear end tapered to fit in the socket, straps bolted to the casting across the pole, and the bolts K through the straps, the pole and the casting.

5. The combination with the pole and roller of a logging-sled, of a casting having a tapering socket or pocket open at the top and front, and the flanges L and N securable to three sides of the roller, and bolts therethrough, said pole having its rear end tapered to fit in the socket, straps bolted to the casting across the pole, and the bolts K through the straps, the pole and the casting, and the draft-hook Q and R, arranged substantially as set forth.

812,311. FIBER-MIXER. EMIL TYDEN, Hastings, Mich. Filed Mar. 18, 1905. Serial No. 250,751.



Claim.—1. In a machine for the purpose stated, in combination with a blending-machine comprising a carrier for feeding material thereto; a plurality of devices for feeding the material to be blended, each of said feeding devices comprising an endless carrier for delivering material therefrom, such carriers being terminated at their delivery side in position for delivering upon said endless feed-carrier of the blending-machine, one in front of another, along the path of movement of the carrying-ply of said carrier, and means for regulating the rate of delivery of the several feeding devices independently of each other.

2. In a machine for the purpose indicated, in combination with a blending-machine comprising an endless carrier for feeding the same; a plurality of devices for feeding the several materials to be blended, each of said feeding devices comprising an endless carrier for delivering the material, said endless carriers of the several feeding devices being arranged successively one above another, each terminating at its delivery side beyond the one below it, above the endless feeding-carrier of the blending-machine, and means for regulat-

ing the rate of delivery of said delivering-carriers independently of each other.

3. In a machine for the purpose indicated, in combination with a blending-machine comprising an endless carrier for feeding the same, a plurality of feeding devices for delivering different materials to said carrier having their delivering means arranged for delivery successively, one in front of another, on said carrier, for producing superimposed layers of the different materials thereon, said feeding devices having variable-speed driving means and means for regulating the speed of each independently of the others.

4. In a mechanical organization for the purpose indicated, in combination with a blending-machine having an endless carrier for feeding it, a plurality of feeding devices, each comprising a receptacle for the material to be fed and means for engaging and carrying away the same, and having each an endless traveling delivery belt or apron, said feeding devices being arranged at successively more and more elevated positions, one behind another, back of the receiving end of the carrier of the blending-machine, the delivery-apron of each feeding device at the rear being extended above all the feeding devices in front of it, said several aprons terminating at their forward or delivery side successively farther and farther forward above the carrier of the blending-machine as they are located successively farther and farther rearward from the receiving side thereof.

5. In a machine for the purpose stated, in combination with a blending-machine comprising a horizontal carrier for feeding material thereto, a plurality of devices for supplying to such carrier the material to be blended, each comprising an endless carrier for delivering material therefrom, such carriers being located one above another, each terminating farther forward than the one below it along the path of movement of said horizontal carrier of the blending-machine.

6. In a machine for the purpose indicated, in combination with a blending-machine comprising a horizontal carrier for feeding the same, a plurality of devices for supplying to such carrier the several materials to be blended, each of said devices comprising an endless carrier for delivering the material, said endless carriers being arranged successively one above another, above the horizontal feeding-carrier of the blending-machine, and each terminating at its delivery side farther forward than the one below it along the path of feeding movement of said blending-machine carrier, and means for regulating the rate of delivery of said several delivering-carriers independently of each other.

812,312. COVERED SPOON. HENRY D. WARD, Worcester, Mass., assignor of one-half to Ira B. Hubbard, Worcester, Mass. Filed Mar. 20, 1905. Serial No. 251,011.

Claim.—1. The combination with the bowl and handle of a spoon, of a cover hinged to the spoon at the junction of the handle and bowl, a bar hinged at one end to said cover, ways on said handle for said bar, and arms at the opposite end of said bar adapted to inclose the thumb of the operator.

2. The combination with the bowl and handle of a spoon, of a hinged cover for said bowl, a slidable bar extending lengthwise said handle, means on the end of said bar for engaging the thumb, and a curved arm on the end of said handle adapted for a finger-rest.

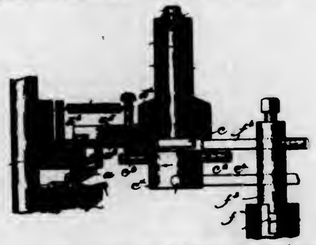
3. As an article of manufacture, a spoon comprising a bowl and handle having its free end upturned, a cover for said bowl hinged at the junction of the bowl and handle, a sliding bar sliding in ways on said handle and pivotally connected with said cover, a bar and upwardly-curved arms on the end of said sliding bar adapted to engage the thumb and an upwardly-curved arm near the end of said handle providing a space between said arm and the upturned end of the handle to receive the forefinger.

812,313. CAST TRUCK-BOLSTER. EDWIN C. WARBURN, Minneapolis, Minn. Filed Mar. 25, 1905. Serial No. 251,948.

Claim.—1. A hollow cast bolster having outwardly-converging upper and lower web portions and having a central longitudinal and vertically-extended web formed with a reinforced rib that extends approximately parallel to the lower web of said bolster and unites with the upper web thereof, substantially as described.

2. A hollow cast truck-bolster having outwardly-converging upper and lower webs and having the vertical longitudinally-extended central web 10 provided on its opposite faces with the transversely-extended reinforcing-ribs 11 and 12, said ribs 11 extending approximately parallel with the bottom web of said bolster and the said rib 12 extending from the top web to the bottom web of said bolster.

812,314. KNITTING-MACHINE. CHARLES H. WHITCHER, Ipswich, Mass. Filed Dec. 23, 1903. Serial No. 186,267.



Claim.—1. In a knitting-machine, the combination with a dial-needle bed, a dial-cam plate and its drawing-in cam, a vertical shaft having a cam, and means to rotate said shaft intermittingly, and devices intermediate the cam on said vertical shaft and the said drawing-in cam that said cam on the vertical shaft may change the position of said drawing-in cam according to the class of knitting to be done.

2. In a knitting-machine having a needle-bed and cam-ring for moving a series of cylinder-needles: a dial-needle bed and dial-cam plate for moving a series of dial-needles to coact with the cylinder-needles, a drawing-in cam for the dial-needles, a vertical shaft having a cam, means acting automatically to rotate said shaft, and means intermediate the cam on said shaft and said drawing-in cam that said shaft as it is rotated may insure two different positions for said drawing-in cam according as it is desired to knit royal-rib or plain-rib stitch.

3. In a knitting-machine having a needle-bed and cam-ring for moving a series of cylinder-needles, a dial-needle bed and dial-cam plate for moving a series of dial-needles to coact with the cylinder-needles, a drawing-in cam for the dial-needles, a slide-bar connected with said drawing-in cam, a vertical shaft having a double-ended cam, a spring acting normally to bear said slide-bar toward said double-ended cam, and means acting automatically to rotate said shaft that its cam may insure two different positions for said slide-bar and the drawing-in cam according as it is desired to knit the royal-rib or plain-rib stitch.

4. In a knitting-machine, a drawing-in cam, a connected slide-bar, a vertical shaft having a cam, and two series of arms below said cam, said arms occupying a position in different horizontal planes, two fingers one coacting with each set of said arms, and a pattern-surface to change the position of one of said fingers to stop the rotation of said cam when only plain-rib knitting is to be done.

5. In a knitting-machine, a drawing-in cam, a connected slide-bar, a vertical shaft having a cam, and two series of arms below said cam, said arms occupying positions in different horizontal planes, a stationary finger coacting with one set of said arms during the knitting of each course of stitches, and a pattern-controlled finger which may be put in position to be struck by the other set of said arms or into a position out of the path of movement of said set of arms to thereby arrest the rotation of the shaft having said cam.

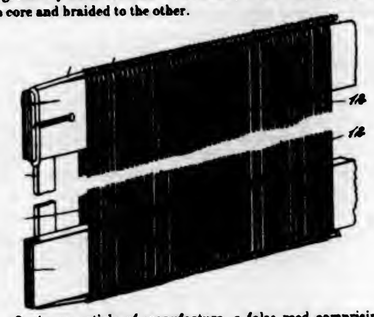
6. In a knitting-machine, a dial-cam plate having a pivoted drawing-in cam, a slide connected with said drawing-in cam, a plate connected with said dial-cam plate and serving as a guide for said slide, a hollow hub, a shaft rotatably mounted in said hub and having a cam and projecting arms, a pattern-surface, a stationary finger, and a movable pattern-controlled finger, the position of the pattern-controlled finger determining whether or not the shaft having said cam shall be rotated intermittingly for the production of a royal-rib stitch, or if said shaft and its cam shall be stopped, for the production of a plain-rib stitch.

812,315. SHOE-TREE. WILLIAM D. WILDER, Brockton, Mass. Filed Apr. 30, 1905. Serial No. 258,568.

Claim.—A shoe-tree comprising a front portion, a heel portion having a longitudinal slot, and a vertical opening intersecting such slot, a link pivotally connected to the front portion of the tree and extending into said longitudinal slot of the heel portion, said link having notches in its lower side, a screw-stem in the vertical opening of the heel portion, recessed on one side to receive the link and having a tooth to engage any of the notches of the link, and a handle, bearing on the heel portion of the tree, having screw-threaded engagement with the screw-stem and forming a nut to move the screw-stem endwise to engage or disengage the link to permit longitudinal adjustment of the heel portion of the tree on the link.

812,316. FALSE REED FOR LOOMS. WILBUR B. WINGATE, Lawrence, Mass., assignor of one-half to Hamson Loom Harness Company, Lawrence, Mass., a Corporation of Massachusetts. Filed Feb. 16, 1905. Serial No. 245,948.

Claim.—1. As an article of manufacture, a false reed comprising two cores and a reed consisting of a cord passed alternately and progressively from one core to the other, said cord being knotted to one core and braided to the other.

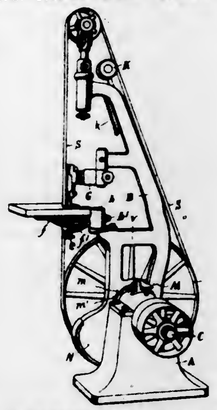


2. As an article of manufacture, a false reed comprising two cores and a reed consisting of a cord passed alternately and progressively from one core to the other, said cord being knotted to one core and braided to the other, and a suitable framework for supporting and maintaining said false reed.

3. As an article of manufacture, a false reed comprising two cores and a reed, the latter consisting of a cord passed alternately and progressively from one core to the other, said cord being bonded to said cores.

4. As an article of manufacture, a false reed comprising two cores and a reed consisting of a cord passed alternately and progressively from one core to the other and bonded to each core at each turn, said cord passing alternately from the front side of one core to the rear side of the other core, and vice versa, and a framework for supporting and maintaining said reed.

812,317. WOODWORKING-MACHINE. OLMEDO C. WYSONG, Greensboro, N. C. Filed Nov. 5, 1904. Serial No. 231,479.



Claim.—1. In a mechanism of the character specified, a base, a frame located at one side thereof and pivoted thereto, said frame being adjustable to varying positions relative to the base, means for locking the frame to the adjusted position, a band-carrying pulley mounted upon a shaft journaled within said pivot, and a band-carrying pulley adjustable relative to said frame.

2. In a mechanism of the character indicated, a base, a frame located at one side thereof and pivoted thereto, said frame being adjustable to varying positions relative to the base, and counterweighted so as to turn freely from one position to another, means for locking the frame to the adjusted position, a pulley mounted upon a shaft journaled within said pivot, an idler-pulley carried by and adjustable relative to the frame.

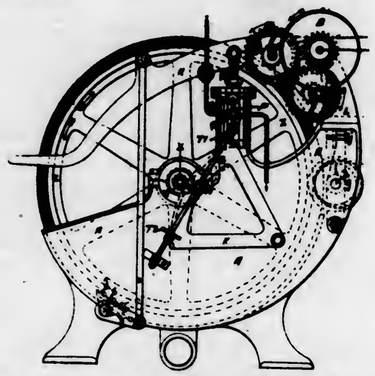
3. In a mechanism of the character indicated, a base, a frame pivoted thereto, a pulley mounted on a shaft journaled in said pivot, a pulley carried by the frame and adjustable relative thereto, a work-table carried by and adjustable relative to said frame.

4. In a band-carrying mechanism a frame journaled to the base, and adapted to be adjusted to varying positions of inclination, a work-carrying table carried by said frame and means for adjusting the table to varying angles, and shifting it into and out of position for use.

5. In a woodworking-machine, a frame provided with band-carrying pulleys and adapted to be adjusted to varying angles of inclination, a work-table, and an adjustable form above said table supporting one face of the band, said work-table and form being carried by said adjustable frame.

6. In a mechanism of the character indicated, a base, a frame pivoted thereto, a pulley mounted on a shaft journaled in said pivot, a pulley carried by the frame and adjustable relative thereto, and a work-table carried by said frame.

812,318. AUTOMATIC DRIVING AND REVERSING MECHANISM. WILLIAM B. YATES, Chicago, Ill. Filed Sept. 19, 1904. Serial No. 225,110.



Claim.—1. A frictional transmission mechanism having a plurality of driving members, a driven member, and fluid-pressure-operated means adapted to alternately bring said driven member into engagement with said driving members.

2. In a driving and reversing mechanism, a plurality of positively-driven friction-rolls rotating in opposite directions, a driven member adapted to contact with said rolls at predetermined intervals, and a fluid-pressure organ for controlling said contact.

3. A driving and reversing mechanism having a plurality of positively-driven friction-rolls rotating in opposite directions, a member adapted to be driven in opposite directions by frictional contact with said rolls and means adapted to cause said contact at predetermined intervals.

4. A friction driving and reversing mechanism having a plurality of positively-driven friction-rolls, a driven member, a fluid-pressure cylinder and piston, and transmission mechanism between said piston and friction-rolls adapted to alternately bring said rolls into driving contact with the driven member.

5. In a friction driving and reversing mechanism, a single power-shaft moving constantly in one direction, a plurality of friction-rolls driven in unison, in opposite directions, by said shaft, swinging journals within which the rolls are mounted, a driven member adapted to receive alternately motion in either direction through contact with the rolls, a fluid-pressure organ connected with the swinging journals of the rolls for the purpose of forcing them alternately into contact with the driven member at predetermined intervals, and means whereby the travel of the driven member admits fluid-pressure to one and the other side of the fluid-pressure organ, causing reversal of the direction of motion at predetermined intervals.

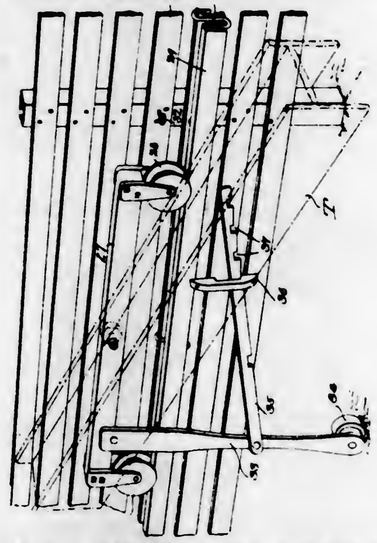
6. In a driving and reversing mechanism, a prime mover running in one direction, a swinging cradle, suitable gearing carried thereby, and friction driving-rolls, with a fluid-pressure mechanism adapted to operate the swinging cradle to give said rolls the necessary pressure for propulsion.

7. In a reversing mechanism, the combination of a prime mover running in one direction, a swinging cradle, suitable gearing carried thereby, and friction driving-rolls, with a valve-operated pressure mechanism adapted to alternate the pressure on said rolls, to give the necessary contact for propulsion in one or the other direction.

8. In a reversing mechanism, the combination of a prime mover running in one direction, and a swinging cradle, suitable positive, power-transmitting gearing and friction driving and pressure-giving mechanism for propulsion carried thereby, with a suitable valve or cock, tappet-rod, tappet-plate, sector or rack carrying a tappet-pin, all operated from the body to be reversed.

9. In a reversing mechanism, the combination of a prime mover revolving in one direction, a swinging cradle, suitable positive, power-transmitting gearing and friction driving and pressure-giving mechanism for propulsion carried thereby, a suitable valve or cock, tappet-rod, tappet-plates, sector or rack carrying a tappet-pin, and a pinion frictionally attached to the body to be reversed, giving movement to the other members, in the manner specified, as and for the purpose described.

812,319. CONVEYER. GILBERT I. SIBBS, Glenavon, Ill. Filed Oct. 18, 1905. Serial No. 283,296.



Claim.—1. A foldable casing, an endless carrier in said casing, shafts supporting the endless carrier, a frame pivoted upon a protruding end of the lower shaft, a driven shaft journaled in the frame, intermeshing bevel-gears upon the driven shaft and the protruding end of the carrier-shaft, an auxiliary shaft journaled in the pivoted frame, a carrier-trough hinged upon said shaft, an endless carrier in the trough supported at one end upon the auxiliary shaft, and means for transmitting motion from the latter to the driven shaft.

2. In a device of the class described, a casing, and a bar pivotally connected with one side of said casing and provided at the ends thereof with track-engaging rollers in combination with an arm pivoted upon the opposite side of the casing, and a ground-engaging wheel at the free end of said arm.

3. In a device of the class described, a casing, a bar pivoted upon one side thereof, track-engaging rollers supported by said bar at opposite sides of the fulcrum of the latter, and a movable supporting-track in combination with an arm pivoted upon the opposite side of the casing and a ground-engaging wheel at the free end of said arm.

4. A casing, rotary track-engaging means connected with one side of the casing, an arm connected pivotally with the other side of the casing, and a ground-engaging wheel at the free end of said arm.

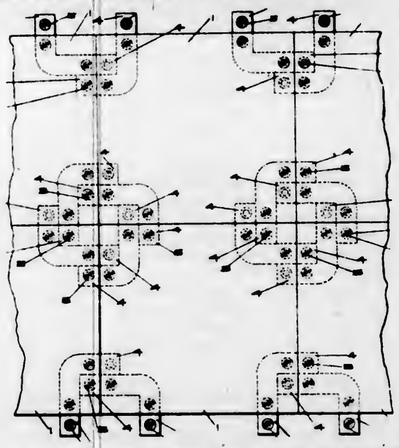
5. A casing, rotary track-engaging means connected with one side thereof, a wheel-carrying arm connected pivotally with the other side of the casing, and means for adjusting said arm and for retaining it at various adjustments.

6. A casing, rotary track-engaging means connected with one side thereof, a wheel-carrying arm pivoted upon the other side of the casing, a notched lever connected pivotally with said arm, and a cleat upon the casing confining said lever and adapted to engage the notches therein.

7. A portable elevator-casing provided upon one side with rotary track-engaging means and upon the other side with rotary ground-engaging means.

8. A portable elevator-casing, rotary track-engaging means connected with one side of the casing, rotary ground-engaging means connected adjustably with the other side of the casing, and a movable track provided with means whereby it may be supported in operative position.

812,320. PARQUET-FLOORING. ROBERT A. ALEXANDER, Meriden, Conn. Filed Aug. 10, 1905. Serial No. 273,654.



Claim.—In a flooring, a series of sections, plates secured to the sections, each of said plates projecting from two sides of the section to which it is attached; each section overlying a plate of every abutting section and having similar plates similarly projecting and adapted to fit under the abutting sections of the flooring as and for the purpose described.

812,321. VEHICLE-TIRE. HUGH R. AULD, Boston, Mass. Filed Feb. 13, 1905. Serial No. 245,264.

Claim.—1. A tire comprising a strip of rubber having flanges upon each side of the tread portion for supporting the retaining-wires, and a stiffener consisting of rigid longitudinal side bars located in the base portion of the tire beneath the flanges with their widest dimensions parallel to the base, there being thick cushions of rubber between the side bars and the wire-engaging surfaces of the flanges, and a cross-bar joined to the side bars and embedded in the rubber.

2. A tire comprising a strip of rubber having flanges upon each side of the tread portion for supporting the retaining-wires, and a stiffener consisting of rigid, flat metallic side bars extending longitudinally of the tire and embedded therein closely adjacent the side and base surfaces thereof, and a cross-bar joined to the side bars, bent sharply toward the tread-surface of the tire and embedded in the rubber, whereby the stiffener is securely connected to the tire and cushions of rubber are provided between the wire-engaging surfaces of the flanges and the side bars of the stiffener.

3. A tire comprising a continuous strip of rubber having a tread portion and a base portion extended on both sides of the tread portion to form flanges for supporting retaining bands or wires, and a stiffener consisting of a rigid metallic frame or grid having side bars extending longitudinally of the tire located at the sides thereof beneath the wire-engaging surfaces of the flanges, and cross-bars joined to the side bars, said cross-bars being displaced at their intermediate portions toward the tread-surface of the tire and separated from each other by relatively wide spaces, whereby they are completely surrounded by and deeply embedded in the rubber of the tire while a thick cushion is provided between the wire-engaging surfaces of the flanges and the side bars.

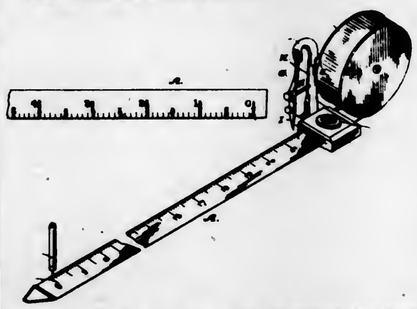
4. A tire comprising a continuous strip of rubber having a tread portion and a base portion extended on both sides of the tread portion to form flanges for supporting retaining bands or wires, a stiffener consisting of a rigid metallic frame or grid embedded in the base portion of the tire, and a fabric covering extending around the base portion of the tire and over the wire-engaging surfaces of the flanges.

5. A rubber tire having a tread portion and a base portion formed with lateral flanges, a fabric covering extending over the side and upper surfaces of the flanges and the sides of the said tread portion adjacent the flanges and vulcanized to the tire, and a stiffener consisting of side bars embedded in the sides of the base portion, extending longitudinally thereof, and a cross-bar joined to said side bars and embedded in the tire.

6. The combination with a wheel-rim channel of a rubber tire formed with a tread portion and a base portion, the latter having flanges projecting beside the tread portion and seated in the rim-channel, retaining-wires surrounding and engaged with the outer surfaces of the said flanges, binding members of frictioned fabric vulcanized to the tire extending over the wire-engaging surfaces of the flanges between the wires and the rubber and upon the sides of the tread portion, the said binding members being carried outward on the sides of the tread portion beyond the wires, whereby the tendency of the flanges to tear away from the body of the tire is resisted, and a stiffener embedded in the base portion beneath and out of contact with the retaining-wires.

7. The combination with a vehicle-wheel rim, of a rubber tire having lateral flanges at its base adapted to seat in the rim and to support longitudinal retaining-wires, stiffening members embedded in the tire close to the base-surface beneath the retaining-wires, and compression members extending transversely of the tire from one stiffening member to the other, connected to hold them apart, and arched to exert the maximum resistance to compression stresses.

812,322. BEAM-COMPASS. THOMAS H. BARKER, Oakland, Cal. Filed July 17, 1905. Serial No. 269,935.



Claim.—1. In a beam-compass, the combination of a beam, a sliding detachable clamp provided with a flat bearing-surface arranged to lie on and slide over the surface to be marked, a post extending upward from the clamp, a tool-holding piece secured thereto, a drawing instrument provided with a marking-point in the plane of the flat bearing-surface of the clamp, a spring-tongue for connecting the drawing instrument to the tool-holding piece, and a screw for adjusting the drawing instrument relatively to the said clamp, substantially as set forth.

2. In a beam-compass, the combination of a flexible beam, a detachable clamp arranged to be adjusted along the said beam, a perpendicularly-arranged post mounted on the clamp, a tool-holding piece connected to the outer end of the post, a drawing instrument, and a spring-tongue for connecting the drawing instrument to the tool-holding piece, the said post, tool-holding piece and drawing instrument being separable from each other, substantially as set forth.

812,323. CHILD'S FOLDING CARRIAGE. WALTER H. BARKER, Harrow, England. Filed Aug. 14, 1905. Serial No. 274,173.

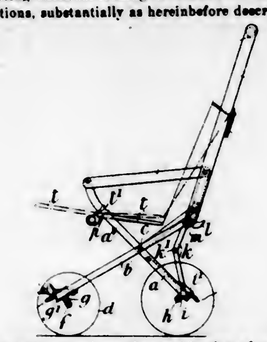
Claim.—1. In a folding carriage, the combination with a pair of hinged frames of traveling wheels mounted upon short axles at-

2. In a hoisting apparatus the combination with an engine having supply and exhaust ports, of adjustable means for partially and

apparatus, nuts having cam-faces and carried by said shaft to be

Claim.—1. In a coin-sorting apparatus, a helical rail on which the coins roll, a vertical or nearly-vertical wall at the external side of

Claim.—1. In a folding carriage, the combination with a pair of hinged frames, of traveling wheels mounted upon short axles attached to brackets hinged to the lower ends of the frames, and means such as a spring-catch for locking the brackets in the extended and folded positions, substantially as hereinbefore described.

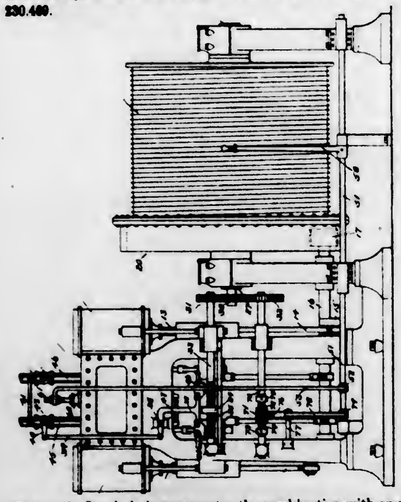


2. In a folding carriage, the combination of a pair of hinged frames, traveling wheels pivoted thereto in such a manner that they can be folded beneath the same, a back-frame secured to one of the hinged frames, arms connecting the back-frame with the other hinged frame and a flexible seat secured to one of the hinged frames and to the back-frame, substantially as described.

3. In a folding chair, the combination of a pair of hinged frames mounted on traveling wheels pivoted with respect thereto, a back-frame rigidly secured to one of the hinged frames, a folding seat, the lower end of which is attached to the other hinged frame and the other end to a wire clip, and of guides upon the back-frame for adjustably securing the wire clip to the back-frame, substantially as hereinbefore described.

4. In a folding chair, the combination of a pair of hinged frames mounted on traveling wheels pivoted with respect thereto, a back-frame rigidly secured to one of the hinged frames, a folding seat, the lower end of which is attached to the other hinged frame and the other end to a wire clip, of guides upon the back-frame for adjustably securing the wire clip to the back-frame, a hinged stay connecting the two hinged frames and a catch for locking the hinged frames in the extended position, substantially as described.

812,324. STEAM HOISTING APPARATUS. GEORGE W. BOLLMAN, Pittsburg, Pa., assignor to Otis Elevator Company, Jersey City, N. J., a Corporation of New Jersey. Filed Oct. 29, 1904. Serial No. 230,469.



Claim.—1. In a hoisting apparatus the combination with an engine having supply and exhaust ports, of automatic means for partially closing both supply and exhaust ports.

2. In a hoisting apparatus the combination with an engine having supply and exhaust ports, of adjustable means for partially and automatically closing both supply and exhaust ports.

3. In a hoisting apparatus the combination with an engine having supply and exhaust ports, of automatic means for partially closing both supply and exhaust ports and then fully closing said ports.

4. In a hoisting apparatus the combination with an engine having supply and exhaust ports, of adjustable means for automatically partially closing both supply and exhaust ports and then fully closing said ports.

5. In a hoisting apparatus, the combination with an engine having supply and exhaust ports, of means for partially closing both supply and exhaust ports, and independent means for thereafter fully closing said ports.

6. In a hoisting apparatus, the combination with an engine having supply and exhaust ports, of adjustable means for partially closing both supply and exhaust ports, and independent means for thereafter fully closing said ports.

7. In a hoisting apparatus, the combination with an engine having supply and exhaust ports, of adjustable means for partially and automatically closing both supply and exhaust ports, and independent automatic means for then fully closing said ports.

8. In combination with hoisting apparatus, of a threaded shaft connected thereto, a traveling pinion on said threaded shaft, limit-stops for said pinion, a gear in mesh with said pinion, and means connected to said gear and operated thereby for slowing down or stopping the hoisting apparatus.

9. In a hoisting apparatus the combination with an engine having supply and exhaust ports, of adjustable means for partially closing both supply and exhaust ports automatically after the engine has made a desired number of revolutions, and independently-adjustable means for fully closing the ports and stopping the engine after the partial closing of said ports.

10. In a hoisting apparatus the combination with an engine having supply and exhaust ports, of an automatic device operated by some moving part of the machine for first partially closing both supply and exhaust ports and then fully closing the ports.

11. In a hoisting apparatus the combination with an engine having supply and exhaust ports, a winding-drum driven by such engine, adjustable means actuated by the movement of the winding-drum for partially closing both supply and exhaust ports automatically after the winding-drum has made a desired movement and independently-adjustable means also driven by the movement of the winding-drum for stopping the engine after such partial closing of said ports.

12. In combination with hoisting apparatus, of a screw-threaded shaft connected to rotate in harmony therewith, a traveling pinion on said shaft and moved along the same longitudinally, limit-stops for changing the longitudinal movement of said pinion to a rotative motion, a gear continually in mesh with said pinion, and means connected with said gear to be operated thereby to slow down or stop the hoisting apparatus upon rotation of said pinion.

13. In hoisting apparatus, the combination with a hoisting-drum, a threaded shaft geared to move with the hoisting-drum, a traveling nut having gear-teeth on its exterior surface, limit-stops for said nut, a segmental gear in mesh with said nut, and means connected with said segmental gear for slowing down or stopping the hoisting-drum when the nut engages a limit-stop.

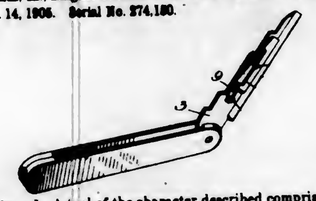
14. In combination with hoisting apparatus, of controlling means therefor, a threaded shaft, a traveler on said shaft, a lever connected to the controlling means, and a cam on said lever in the path of said nut.

15. In combination with hoisting apparatus, of controlling means therefor, a threaded shaft connected to rotate in harmony with the movement of the hoisting apparatus, a traveling nut on said threaded shaft, means for restricting said nut to a longitudinal movement, a lever connected to said controlling means, and cams at predetermined points in the path of travel of said nut to effect the operation of said controlling apparatus at corresponding positions of the hoisting apparatus.

16. In combination with hoisting apparatus, of controlling means therefor, a threaded shaft connected to said hoisting apparatus, a longitudinally-traveling nut on said shaft, a pivoted lever, cams on two of the arms of said lever and in the path of travel of said nut to be engaged by said nut at the limits of movement of said hoisting apparatus, and means coacting with a third arm of said lever for operating said controlling apparatus to slow down or stop said hoisting apparatus.

17. In combination with hoisting apparatus, of means for controlling same, a threaded shaft rotatively connected to said hoisting apparatus, nuts having cam-faces and carried by said shaft to be moved longitudinally, a pivoted lever having arms in the path of travel of said nuts to be engaged by said cam-faces at predetermined times, and means coacting with said lever for operating said controlling means for slowing down or stopping said hoisting apparatus when a cam engages said lever.

812,325. CUTTING AND REAMING KNIFE. WILLIAM BROWER, Manlius, Ill., assignor of one-half to Max P. Seibel, Manlius, Ill. Filed Aug. 14, 1905. Serial No. 274,180.



Claim.—1. A tool of the character described comprising a handle, a tapering blade connected to said handle, said blade having one of its edges turned or bent longitudinally, and a series of notches arranged in the opposite edge of said blade to form parallel offset cutting edges, substantially as described.

2. A tool of the character described comprising a handle a tapering blade connected to said handle, said blade having formed therein a longitudinally-disposed slot, and having one of its edges turned or bent longitudinally, a series of notches arranged in the opposite edge of said blade to form offset, parallel cutting edges, and a plate adjustably mounted on one side of said blade to slide over the slot in the latter, substantially as described.

3. A tool of the character described comprising a handle, a slotted blade pivotally connected to said handle to close therein, one edge of said blade being obliquely disposed or tapered toward the point of the same, a series of offset cutting edges formed in said oblique edge, a laterally-projecting flange formed on the straight back edge of said blade and a plate adjustably secured to the former to slidably engage said flange, substantially as described.

812,326. RECOIL-BRAKE FOR AUTOMATIC GUNS. JOHN M. BROWNING, Ogden, Utah. Filed June 30, 1904. Serial No. 214,773.

Claim.—1. In an automatic gun, the combination with a recoiling barrel, a friction-brake connected with the barrel and operating through the recoiling movement of the barrel for reducing the shock of recoil, and means separate from the barrel for increasing the friction of said brake upon the firing of the gun.

2. In an automatic gun, the combination of a recoiling barrel, a magazine, a friction-brake connected to the barrel to move rearward therewith and reduce the shock of recoil, and auxiliary means separate from the barrel for increasing the friction of said brake on the magazine upon the firing of the gun.

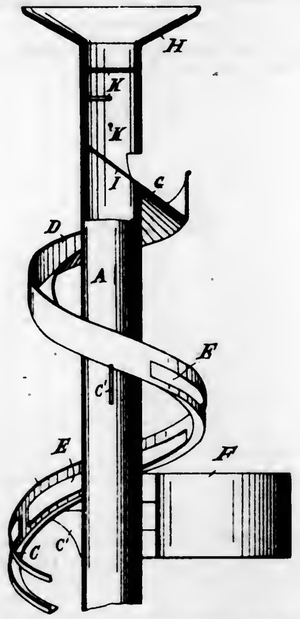
3. In an automatic gun, the combination with a recoiling barrel, of a tubular magazine, a friction-brake connecting with the magazine over which it rides to reduce the shock of recoil, and auxiliary means separate from the barrel for increasing the friction of the brake on the magazine upon the firing of the gun.

4. In an automatic gun, the combination with a recoiling barrel, of a friction-brake connected with the barrel and reducing the shock when the barrel is recoiling, and braking the shock following the return of the barrel to firing position, and auxiliary means independent of the barrel and removable from the brake, for regulating the friction of said brake upon the firing of the gun.

5. An automatic gun, a recoiling barrel, a split collar connected thereto, a rigid piece parallel with the barrel and surrounded by said collar, the spring for returning the barrel, and a beveled ring pressed by said spring against said collar to contract the same.

812,327. APPARATUS FOR SORTING OR SEPARATING COINS. BJARNE CRAMHEIM, Kongsberg, Norway. Filed Mar. 27, 1905. Serial No. 252,294.

Claim.—1. In a coin-sorting apparatus, a helical rail on which the coins roll, a vertical or nearly-vertical wall at the external side of said rail having coin-apertures therein, and means to give the coins such inclined position relatively to the axis of the helical rail that they are automatically lifted to roll on edge under the influence of the centrifugal force.



2. In a coin-sorting apparatus, a helical rail on which the coins roll, a vertical or nearly-vertical wall at the external side of said rail having coin-sorting apertures therein, and an incline to give the coins such inclined position relatively to the axis of the helical rail that they are automatically lifted to roll on edge under the influence of the centrifugal force.

3. In a coin-sorting apparatus, a helical rail on which the coins roll, a vertical or nearly-vertical wall at the external side of said rail having longitudinal coin-sorting apertures therein, and an incline at the upper end forming a continuation of the rail adapted to give the coins such inclination relatively to the axis of the rolling-path that they are automatically lifted to roll on edge under the influence of the centrifugal force.

4. In a coin-sorting apparatus, a helical rail, a vertical or nearly-vertical wall at the external side of said rail having longitudinal coin-sorting apertures therein, the successive apertures increasing in height, and a continuation of the rail at the upper end having such inclination as to cause the coins to be automatically lifted to roll on edge under the influence of the centrifugal force.

5. In a coin-sorting apparatus, a post, a helical rail carried by the same, a wall at the outer edge of the rail having coin-sorting apertures therein, a chute on the post having a bottom to direct coins onto the rail and of such inclination as to cause the coins to automatically turn on edge under the influence of the centrifugal force given by the rail.

6. In a coin-sorting apparatus, a post, a chute mounted thereon, means in the chute to prevent the coins from choking the same, a vertical or nearly-vertical wall, an inclined helical rail connecting the chute and wall, said chute and rail having such inclination as to cause the coins to automatically turn on edge under the influence of the centrifugal force given by the rail.

7. In a coin-sorting apparatus, a central post, a hopper mounted thereon, a chute fed from said hopper, cross-bars in the chute, an inclined bottom in said chute, a helical rail forming a continuation of said bottom and supported by said post, a vertical or nearly-vertical wall at the outer edge of said rail and having longitudinal coin-sorting apertures therein.

8. In a coin-sorting apparatus, a central hollow post having a

lateral aperture near its top, a hopper mounted on the top, cross-bars mounted in the post beneath the hopper, an incline in the post beneath the cross-bars, a helical rail mounted on the exterior of the

812,880. LUBRICATOR. CHARLES C. DODGE, Newark, N. J., assignor to The Dodge Lubricator Company, Boston, Mass., a Corporation of Massachusetts. Filed Oct. 16, 1905. Serial No. 283,261.

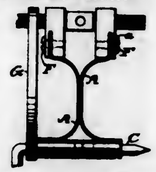
teeth on its periphery to be engaged by said operating-stem, substantially as described.

9. In a lubricator such as described, the combination of a res-

box, and means for drawing the pieces toward each other against the resistance of the resiliency of the strips.

lateral aperture near its top, a hopper mounted on the top, cross-bars mounted in the post beneath the hopper, an incline in the post beneath the cross-bars, a helical rail mounted on the exterior of the post and forming a continuation of the incline, a vertical or nearly-vertical wall at the outer edge of said rail having longitudinal coin-entering slots therein, and a receptacle supported by the post in close proximity to each slot to receive the coins falling through said slots.

812,828. DENTAL MATRIX. WILLIAM CHENOWAW, Atlanta, Ga. Filed Nov. 10, 1905. Serial No. 286,691.

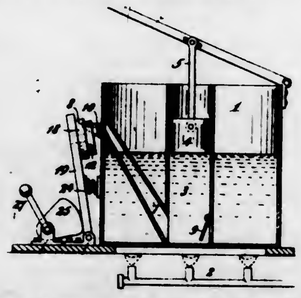


Claim.—1. A dental matrix comprising flexible members, means connecting and coöperating with said members for placing them under tension, and a rigid bow-brace having detachable connection with said matrix for imparting rigidity to the same.

2. A dental matrix comprising a pair of flexible members, means connecting said members at their opposite ends, means for placing said members under tension, and a rigid bow-brace connecting the opposite ends of one of said members.

3. A dental matrix comprising a pair of flexible members connected at their opposite ends, each member consisting of a nut formed with a slot extending from the front and parallel with the sides thereof and a flexible band, one end of which is adapted to fit in the slot of said nut, and means, such as a screw, for detachably connecting the band and nut.

812,829. APPARATUS FOR APPLYING MOLTEN SOLDER TO SHEET METAL, CAN-CAPS, &c. WILLIAM G. DAUGHERTY, Baltimore, Md. Filed Oct. 18, 1905. Serial No. 283,253.



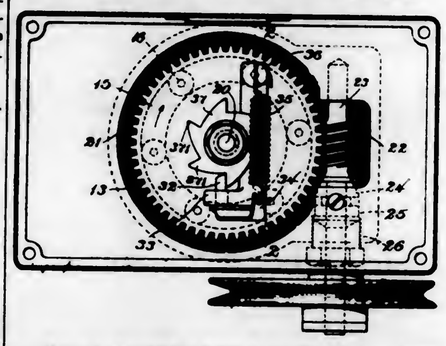
Claim.—1. In an apparatus for applying molten solder to sheet metal, can-caps and other articles, the combination of a holding means for the article having an inclosed space next to the surface of the article, which space limits the extent of the surface of the article which receives the molten solder, and means for forcing molten solder into said space and against the said surface of the article, substantially as and for the purposes described.

2. In an apparatus for applying molten solder, the combination of separable dies between which the can-cap or other article is held, one of said dies having a space which is inclosed by the die and by the solder-receiving surface of the article, and means for forcing molten solder into said space and against said surface of the article, substantially as and for the purposes described.

3. In combination with a mold or receptacle for holding the can-cap or similar article with only that portion of the article exposed where the solder is to be applied, means for forcing solder into said receptacle, substantially as set forth.

4. In an apparatus for applying molten solder, the combination of a mold or receptacle for holding the can-cap or other article with only that portion of the article exposed where the solder is to be applied, a device for forcing solder into said receptacle, and means for bringing together and for separating the said receptacle and the solder-forcing device, substantially as set forth.

812,830. LUBRICATOR. CHARLES C. DODGE, Newark, N. J., assignor to The Dodge Lubricator Company, Boston, Mass., a Corporation of Massachusetts. Filed Oct. 16, 1905. Serial No. 283,281.



Claim.—1. In a lubricator such as described, the combination with a reservoir for the lubricant having a plurality of discharge-ducts, of a rotary pump-carrier and pump located in the reservoir and having a duct adapted to register successively with the first-mentioned ducts, an arbor on which the said pump-carrier is supported, and a fixed cam on said arbor having projections for operating the pump, and means for rotating the carrier.

2. In a lubricator such as described, the combination with a reservoir for the lubricant having a plurality of discharge-ducts whose mouths are in the same plane, of a carrier having a flat under face and having a duct adapted to register successively with the discharge-ducts, a pump extending across the said carrier, means for rotating the carrier, and means for operating the pump.

3. In a lubricator such as described, the combination with a reservoir having a plurality of annular bosses, with discharge openings or ducts, said bosses all having their faces in the same plane, of a rotary pump-carrier located in the reservoir and having a flat bottom face seated upon said bosses, said carrier having a pump and a duct from said pump adapted to register successively with the said openings, and means for rotating the carrier and operating the pump.

4. In a lubricator, such as described, a reservoir having a base with a cup-shaped depression, said depression having in its bottom a series of bosses with outlet-ducts therethrough, a rotary pump-carrier arranged in the cup-shaped depression and seated upon said bosses and having a pump discharge-duct adapted to register successively with the outlet-ducts, a pump on said carrier, and means for rotating the carrier and operating said pump.

5. In a lubricator such as described, a reservoir having a base provided with a series of outlet-ducts, a fixed arbor secured to said base, a pump-carrier mounted to turn on said arbor and having a pump discharge-duct adapted to register successively with said outlet-ducts, a cam fixed against rotation on said arbor and having cam-teeth, a pump on said carrier whose plunger is adapted to be controlled by said cam-teeth, and means for rotating said carrier.

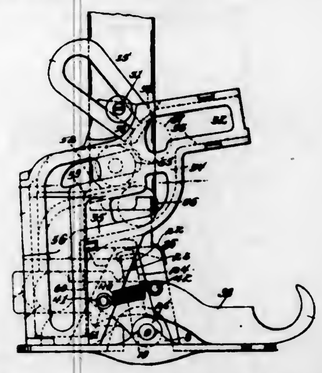
6. In a lubricator, such as described, a reservoir having its base provided with a series of outlet-ducts, an arbor, a pump-carrier rotatable on said arbor and seated against the mouths of said outlet-ducts, said carrier having a pump discharge-duct adapted to register successively with said outlet-ducts, a pump on said carrier comprising a cylinder and a piston, an operating-stem connected to said piston, a spring for moving the piston in one direction, a cam supported by said arbor and held thereby against rotation for moving the piston in the opposite direction, and means for rotating said pump-carrier.

7. In a lubricator, such as described, the combination with a reservoir-base having outlet-ducts, of a fixed upright arbor, a pump-carrier rotatable on said arbor and seated against said outlet-ducts, said carrier having a pump and a pump discharge-duct adapted to register successively with said outlet-ducts, a non-rotary cam mounted on said arbor above said pump-carrier and having teeth on its periphery for operating said pump, an adjustable abutment on said arbor, and a spring interposed between said abutment and said cam for yieldingly forcing said carrier against its seat.

8. In a lubricator, such as described, the combination of a reservoir-base, an upright arbor fixed to said base, a rotary carrier journaled on said arbor, a horizontal pump on said carrier to one side of said arbor, an operating-stem connected to the pump-plunger and arranged radially of the carrier, and a disk on said arbor having cam-teeth on its periphery to be engaged by said operating-stem, substantially as described.

9. In a lubricator such as described, the combination of a reservoir-base, an upright arbor fixed to said base, a rotary carrier journaled on said arbor, a horizontal pump on said carrier on one side of said arbor, a horizontal operating-stem for the pump-plunger, and fixed projections with which said stem coöperates to control the plunger.

812,831. COIN-CONTROLLED APPARATUS. FREDERICK J. DOLE, New York, N. Y., assignor to The Great American Automatic Vending Machine Company, Hoboken, N. J., a Corporation of New Jersey. Filed Dec. 30, 1904. Serial No. 238,888.



Claim.—1. In a coin-controlled apparatus having a coin-slot, the combination of an operating-bar having an abutment-face for engaging the edge of a coin passed through such slot, a rocking plate having an abutment-face for the engagement of the opposite edge of the coin for rocking said plate when the bar is advanced, means for returning the bar to initial position, and means for returning the plate to initial position after the bar has been partially returned, whereby the resulting separation of the abutment-faces of such plate and bar will release the coin.

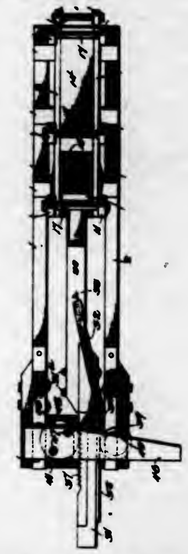
2. In a coin-controlled apparatus, having a coin-slot, the combination of an operating-bar having an abutment-face for engaging the edge of a coin passed through such slot, a rocking plate having an abutment-face for the engagement of the opposite edge of the coin for rocking said plate when the bar is advanced, means for returning the bar to initial position, and means for returning the plate to initial position after the bar has been partially returned, whereby the resulting separation of the abutment-face of such plate and bar will release the coin, and for striking the coin for displacing it from an operative position.

3. In a coin-controlled apparatus having a coin-slot, the combination of an operating-bar having an abutment-face for engaging the edge of a coin passed through such slot, the said face being convex with the chord of the arc disposed substantially vertical, the curvature corresponding approximately to that of the coin, a rocking plate having an abutment-face for engagement by the opposite edge of the coin to be thereby rocked when the bar and coin are advanced, means for returning the bar to initial position, and means for returning the plate to initial position after said bar has been partially returned, whereby the resulting separation of the said abutment-faces will release the coin.

812,832. HAY-BALING PRESS. DEMPSEY S. ROSENFIELD, Savannah, Ga., assignor of one-half to J. Lawton Hiers, Savannah, Ga. Filed Feb. 9, 1903. Serial No. 142,574.

Claim.—1. In a baling-press, the combination with a plunger-head and its actuating mechanism, of a press-box frame provided with flexible resilient metallic strips upon its respective sides, tail-frame side pieces carried by the projecting ends of said strips in the rear of the box, and means for drawing the frame side pieces toward each other.

2. In a baling-press, the combination with a plunger-head and its actuating mechanism, of a press-box frame provided with a pair of resilient metallic strips upon its respective sides, tail-frame side pieces carried by the projecting ends of said strips in the rear of the box, and means for drawing the pieces toward each other against the resistance of the resiliency of the strips.



3. In a baling-press, the combination with a plunger-head, its actuating mechanism, and a press-box frame provided with side pieces and a plurality of pairs of oppositely-disposed uprights, of flexible resilient metallic strips upon opposite sides of the press-box frame and secured respectively to the forward uprights and projecting beyond the rearward uprights, tail-frame side pieces carried by the projecting ends of said strips respectively in the rear of the box, and means for drawing the tail-frame side pieces toward each other.

812,833. SIEVE. AXEL W. ERSTROM, Stanton, Iowa. Filed July 6, 1905. Serial No. 268,563.

Claim.—1. A wire sieve having two sets of parallel wires, one of said sets comprising every other wire, said sets being normally in the same plane, and means for throwing one set out of plane with the other to thereby increase the spaces between the wires, said sets having cross-wires embracing each of the parallel wires to steady them against lateral displacement.

2. A wire sieve having two sets of parallel wires, one of said sets comprising every other wire, said sets being normally in the same plane, and means for throwing one set out of plane with the other to thereby increase the spaces between the wires, said sets having cross-wires embracing each of the parallel wires to steady them against lateral displacement, and means for stretching the parallel wires, substantially as set forth.

3. A wire sieve having two sets of parallel wires, one of said sets comprising every other wire, said sets being normally in the same plane and means for throwing one set out of plane with the other to thereby increase the spaces between the wires, said means consisting of cam-bars journaled in the frame of the sieve and having deep notches for every other wire and shallow notches for every other wire and means for rocking the cam-bars simultaneously.

4. A wire sieve having two sets of parallel wires, one of said sets comprising every other wire, said sets being normally in the same plane, and means for throwing one set out of plane with the other to thereby increase the spaces between the wires, said means consisting of cam-bars journaled in the frame of the sieve and having deep notches for every other wire and shallow notches for every other wire and means for rocking the cam-bars simultaneously, said rocking means consisting of rocker-arms on the cams, a rod pivotally connecting said rocker-arms together, a thumb-nut on one end of the rod and a retracting-spring at the other end.

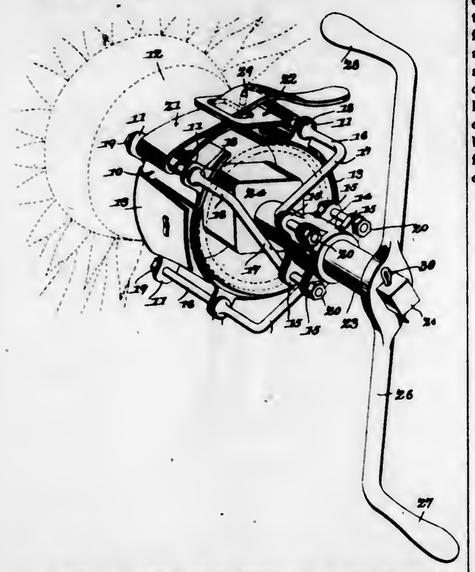
812,834. HUB-WRENCH. MARSHALL P. EDWARDS, Stillwater, Okla. Filed Mar. 9, 1905. Serial No. 249,260.

loose driving-pulley, said driving-pulley being provided with a clutch member, the clutch member on the shaft, slidable thereon and

pivotally attached to the rod, and means for holding the lever against movement, substantially as and for the purpose specified.

Claim.—1. A float-valve, comprising an open-ended casing having a straight cylindrical bore formed at one end with a valve-seat,

812,334. HUB-WRENCH. MARSHALL P. EDWARDS, Stillwater, Okla. Filed Mar. 9, 1905. Serial No. 249,289.



Claim.—1. A hub-wrench comprising a divided flexible hub-embracing band, means for binding the band upon a hub, an open-ended sleeve disposed at one side of the band and in line with the longitudinal axis thereof, connecting means between the sleeve and the band to automatically maintain the former in axial alinement with the band, and a wrench having a shank portion slidable through and rotatable in the sleeve.

2. A hub-wrench comprising a divided resilient band, a strap connected to the ends of said band for binding the same on a wheel-hub, and a wrench rotatively disposed relative to said band and movable toward and away from the same.

3. A hub-wrench comprising a divided resilient band, means for binding said band on a wheel-hub, a wrench for bearing over the binding-nut of the axle end and having a stock extending from the same, a sleeve in which said stock is slidably and rotatively disposed, and means for movably connecting said sleeve to said band.

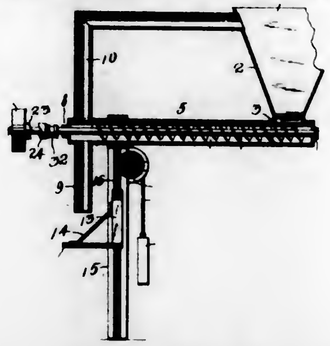
4. In a hub-wrench, a divided band having means for binding on a wheel-hub, a sleeve disposed centrally of said band, spaced rods rotatively connected to said band and to said sleeve and with lateral offsets between the band and sleeve, and a wrench-stock rotatively and slidably engaging said sleeve for engagement with the nut of the wheel.

5. In a hub-wrench, a divided band having means for binding on a wheel-hub and with spaced ears extending laterally from the ends, a sleeve disposed centrally of said hub and having spaced lateral ears, spaced rods mounted for rotation in said band-ears and in said sleeve-ears and each provided with a lateral offset between the band and sleeve, and a wrench member mounted for rotation in said sleeve and slidable through the same

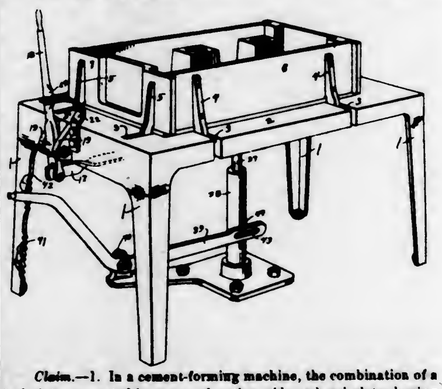
6. A hub-wrench comprising a divided flexible band, means to clamp the same upon a hub, an annular series of rods disposed in substantial parallelism with the axis of the band and rotatably mounted upon the exterior of the band, said rods being projected at one edge of the band and provided with crank-terminals, an open-ended sleeve located between and loosely carried by the crank-terminals of the rods, and a wrench element having a shank rotatable within and movable endwise through the sleeve.

812,335. SACK-FILLING MACHINE. JAMES J. FERGUSON and SIMON P. OSWALD, Nashville, Tenn. Filed July 3, 1905. Serial No. 268,126.

Claim.—The herein-described sack-filling machine comprising the hopper, the conveyer-tube into which the hopper discharges, the conveyer-worm in said tube, having the shaft provided with the loose driving-pulley, said driving-pulley being provided with a clutch member, the clutch member on the shaft, slidable thereon and connected thereto for revolution therewith, the upright guide-frame, the platform guided by the said frame, the shaft mounted on said frame, above said platform and having pulleys of unequal diameter, a cable wound on one of said pulleys and connected to the platform, a cable wound in the reverse direction on the other of said pulleys, a counterweight attached to the last-mentioned cable, the bell-crank lever mounted on the guide-frame, connections between the bell-crank lever and the shiftable clutch member, the spring acting on the bell-crank lever to normally disengage the shiftable clutch member from that of the driving-pulley, and means connected to the bell-crank lever to move the latter against the tension of said spring.



812,336. MACHINE FOR FORMING CONCRETE BLOCKS. EMERSON C. GLATFELTER, New Philadelphia, Ohio. Filed Aug. 23, 1905. Serial No. 275,402.



Claim.—1. In a cement-forming machine, the combination of a bed-plate supported in proper elevation, side and end plates having secured thereto arms, and the arms pivotally connected and extended below the bed-plate, a sleeve mounted upon a bearing and its upper end provided with a head, and bars located at right angles to each other, links secured to said bars and plate-bars adapted to be operated by the links connected to the right-angled bars, and a lever adapted to oscillate or rock the right-angled bars, and means for holding the lever in fixed adjustment, and a rod connected to the lever and to one of the right-angled bars, substantially as and for the purpose specified.

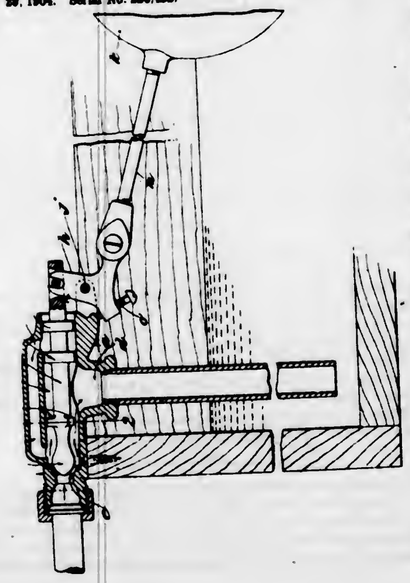
2. In a machine of the class described, the combination of a suitable bed-plate, side and end mold-plates, bars secured to said end and side mold-plates and extended below said plates means for adjusting the side and end plate bars, and holding said bars in fixed adjustment, means for rocking the side and end mold-plates, a follower normally located upon the bed-plate, a spider or head, a reciprocating rod adapted to support said spider or head, and the spider or head provided with pins adapted to engage the bottom or under side of the follower, said spider or head secured to the reciprocating rod, a hollow standard adapted to receive the reciprocating rod, a lever pivotally attached to the rod, and means for holding the lever against movement, substantially as and for the purpose specified.

3. In a machine of the class described, the combination of a bed-plate supported in proper elevation, a bearing extended from below the bed-plate and a rotating sleeve mounted thereon, said rotating sleeve provided with a head, grooves formed in the head and in the bed-plate, antifriction-balls located in the grooves and the head of the sleeve provided with bars, said bars located at right angles to each other, side and end mold-plates provided with pivoted arms, bars pivotally attached to the lower ends of the pivoted arms, and links secured to the right-angled bars, and the right-angled bars secured to the head of the rotating sleeve at their inner ends and their outer ends secured to the bars connected to the pivoted arms, an operating-lever having connected at its lower end an operating-rod, said operating-rod connected at its opposite end to one of the right-angled bars secured to the head, substantially as and for the purpose specified.

4. In a machine of the class described, the combination of a bed-plate supported in proper elevation, a bearing extended from below the bed-plate, a rotating sleeve mounted thereon, said rotating sleeve provided with a head, grooves located in the head and in the bed-plate, antifriction-balls located in the grooves and the head of the sleeve provided with bars, said bars located substantially at right angles to each other, side and end mold-plates provided with pivoted arms, bars pivotally attached to the lower ends of the pivoted arms, links secured to the bars fixed to the head of the rotating sleeve at their inner ends, and their outer ends secured to the bars connected to the pivoted arms fixed to the mold-plates, an operating-lever having connected at its lower end an operating-rod, said operating-rod connected at its opposite end to one of the bars fixed to the rotating head and means for adjusting the side and end mold-plates to and from each other, substantially as and for the purpose specified.

5. In a machine of the class described, the combination of a bed-plate supported in proper elevation, side and end mold-plates provided with pivoted arms bars connected to the lower ends of the pivoted mold-plate arms, means for actuating the pivoted arms upon their pivotal points, a follower located upon the bed-plate, a spider provided with pins and the pins adapted for contact with the lower face of the follower, said spider secured to a reciprocating rod, a hollow standard adapted to receive the reciprocating rod, a spring located below the reciprocating rod and within the hollow standard and means for reciprocating the rod and the spider, substantially as and for the purpose specified.

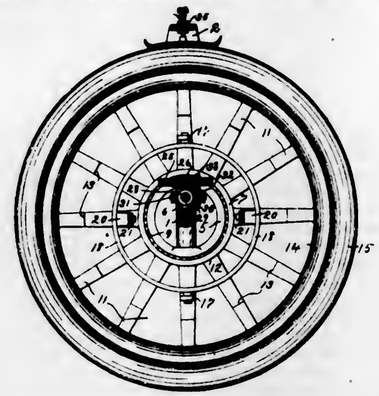
812,337. FLOAT-VALVE. WILLIAM GRAY, Springfield, Mass., assignor of one-half to James C. Robertson, Springfield, Mass. Filed Sept. 29, 1904. Serial No. 226,433.



Claim.—1. A float-valve, comprising an open-ended casing having a straight cylindrical bore formed at one end with a valve-seat, said casing being further provided with an intermediate outlet, and with a separate suction-passage in communication with the bore contiguous to the valve-seat and at a point between one open end and the outlet, a packingless float-operated plunger arranged within the bore and provided at one end with a valve, and at the opposite end portion with a head loosely fitting the open end of the casing.

2. A float-valve, comprising an open-ended casing having a straight cylindrical bore formed at one end with a valve-seat, said casing being further provided with an intermediate outlet, and with a separate longitudinal suction-passage paralleling the bore and in communication with the latter contiguous to the valve-seat and also at a point between one open end and the outlet, and a packingless float-operated plunger arranged within the bore and provided at one end with a valve, and at its opposite end portion with a pair of spaced heads both located at one side of the plane of the outlet.

812,338. MOTOR-DRIVEN VEHICLE. HANS T. HANSEN, Wauwatosa, Wis. Filed Apr. 15, 1905. Serial No. 255,703.



Claim.—1. In a vehicle of the described class, the combination of a central fixed axle-shaft provided with vertically-extending pivot-studs; an oscillatory ring mounted on said pivot-studs; a wheel having its hub rotatably mounted on said ring; and driving mechanism having universal-joint connection with the wheel exterior to the hub and substantially in the plane of the wheel-rim.

2. In a vehicle of the described class, the combination of a centrally-pivoted wheel-support; a wheel-hub rotatable on said support; a wheel connected with the outer end of the hub and dished inwardly; and driving mechanism having universal-joint connection with the wheel between the hub and rim.

3. In a vehicle of the described class, the combination of a central pivoted wheel-support; a wheel-hub rotatable on said support; a wheel connected with the outer end of the hub and dished inwardly; and driving mechanism having universal-joint connection with the wheel between the hub and the rim; together with means for steering said wheel.

4. In a vehicle of the described class, the combination of a wheel having spokes connected with the outer end of the hub and offset inwardly at an intermediate point; a ring pivotally connected on opposite sides with two of the spokes, substantially in the plane of the wheel-rim; and a driving member having arms pivotally connected with said ring on opposite sides and at right angles to the line of wheel connection.

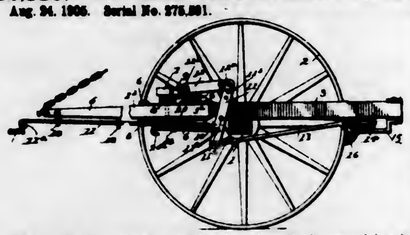
5. In a vehicle of the described class, the combination of a central fixed axle-shaft; an oscillatory ring supported from the shaft by vertical pivot-bearings; a wheel rotatably mounted on said ring; and driving mechanism having universal-joint connection with the wheel, between said ring and the rim of the wheel.

6. In a vehicle of the described class, the combination of a central fixed axle-shaft; an oscillatory ring supported from the shaft by vertical pivot-bearings; a wheel rotatably mounted on said ring; and driving mechanism having universal-joint connection with the wheel between said ring and the rim of the wheel; together with means mounted on the stationary shaft, for oscillating said ring.

7. In a vehicle of the described class, the combination of a central fixed axle-shaft; an oscillatory ring supported from the shaft by vertical pivot-bearings; a wheel rotatably mounted on said ring; and driving mechanism having universal-joint connection with the wheel between said ring and the rim of the wheel; together with a toothed segment mounted on said ring, and gear connections for transmitting motion to oscillate the ring through said segment.

8. In a vehicle of the described class, the combination of a central fixed axle-shaft; an oscillatory ring supported from the shaft by vertical pivot-bearings; a wheel rotatably mounted on said ring; and driving mechanism having universal-joint connection with the wheel between said ring and the rim of the wheel; together with means for oscillating said ring.

812,339. **WAGON-BRAKE.** JACOB HAPPEL, Anchorage, Ky. Filed Aug. 24, 1905. Serial No. 275,501.

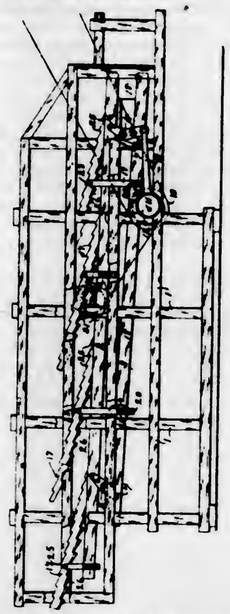


Claim.—1. A mechanism of the class described, comprising in combination with the wheeled axle, hounds secured thereto with their front ends spaced apart to form a channel, bridge-pieces secured to said hounds to bridge said channel, a tongue mounted between said bridge-pieces and said hounds in said channel and capable of longitudinal movement, a hammer-pin and a cross-tree secured to said tongue, a hammer-strap secured to said tongue and said hammer-pin, a lever pivotally secured to said axle, a rod connecting one end of said lever with said hammer-strap, a brake-beam having brake-shoes slidably mounted on said hounds, a rod connecting said brake-beam to the other end of said lever, a second rod secured to said other end of said lever and passing along the under side of the tongue, said second rod having a hook for engaging with the traces of the harness at times, substantially as shown and described.

2. A mechanism of the class described, comprising in combination with a wheeled axle, hounds secured thereto with their front ends spaced apart to form a channel, bridge-pieces secured to said hounds to bridge said channel, a tongue mounted between said bridge-pieces and said hounds in said channel and capable of longitudinal movement, a hammer-pin and a cross-tree secured to said tongue, a hammer-strap secured to said tongue and said hammer-pin, a lever pivotally secured to said axle, a rod connecting one end of said lever with said hammer-strap, a brake-beam having brake-shoes slidably mounted on said hounds, a rod connecting said brake-beam to the other end of said lever, a second rod secured to the other end of said lever and passing along the under side of the tongue, said second rod having a hook for engaging with the traces of the harness at times, a third rod secured to said axle, and passing under said tongue and extending to the front thereof, means for securing a supplemental tree to said third rod, to which a third horse may be secured without interfering with the operation of the pivoted lever and the tongue, all being arranged substantially as shown and described.

3. A mechanism of the class described, comprising in combination with a wheeled axle, hounds secured thereto with their front ends spaced apart to form a channel, bridge-pieces secured to said hounds to bridge said channel, a tongue mounted between said bridge-pieces and said hounds in said channel and capable of longitudinal movement, a hammer-pin and a cross-tree secured to said tongue, a hammer-strap secured to said tongue and said hammer-pin, a lever pivotally secured to said axle, a rod connecting one end of said lever with said hammer-strap, a brake-beam having brake-shoes slidably mounted on said hounds, a rod connecting said brake-beam to the other end of said lever, a second rod secured to the other end of said lever and passing along the under side of the tongue, said second rod having a hook for engaging with the traces of the harness at times, a third rod secured to said axle, and passing under said tongue and extending to the front thereof, means for securing a supplemental tree to said third rod, to which a third horse may be secured without interfering with the operation of the pivoted lever and the tongue, and means for locking said tongue from longitudinal movement at times, substantially as shown and described.

812,340. **SEPARATOR.** HENRY M. HARDENOVER, Madison, Wis. Filed Apr. 3, 1905. Serial No. 253,566.



Claim.—1. In a separator of the described class, the combination of a vibratory frame; straw-supporting devices mounted on said frame; and a set of beaters arranged to project upwardly between the straw-supporting devices; each of said beaters consisting of a rotary straight-sided rectangular plate, arranged in such relation to the frame that its corners will project above the straw-supporting devices successively as the plate is rotated; said plates being exposed above such devices at varying distances during the vibration of the frame.

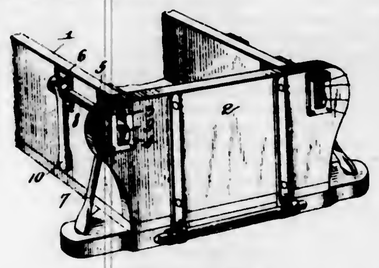
2. In a separator of the described class, the combination of a set of superposed vibratory frames; supporting cross-shafts mounted on stationary bearings between said frames, and provided with arms connected with each of the frames; means for vibrating said frames into and out of proximity with each other; a series of inclined straw-supporting toothed bars mounted on each of said frames, with the bars of one frame having raised rear end portions projecting a substantial distance over the lower front end portions of the bars on the other frame, in all positions of frame adjustment.

3. In a separator of the described class, the combination of a vibratory frame; toothed straw-supporting bars arranged in sets on said frame; and a set of beaters arranged to project upwardly between the toothed bars of one of the sets of bars; each of said beaters consisting of a rotary straight-sided rectangular plate, arranged in such relation to the bars that its corners will project above the bars successively as the plate is rotated; said plates being exposed above the bars at varying distances during the vibration of the frame.

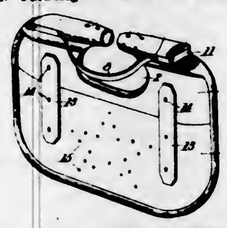
4. In a separator of the described class, the combination of a set of vibratory frames; toothed straw-supporting bars arranged in sets on each of said frames; and a set of beaters arranged to project upwardly between the toothed bars of one of the sets of bars; each of said beaters consisting of a rotary straight-sided rectangular plate arranged in such relation to the bars that its corners will project above the bars successively as the plate is rotated, and at varying distances dependent upon the position of the bars; the bars between which said beaters extend being arranged in pairs, one on each side of each beater and in comparatively close proximity thereto.

812,341. **FASTENING DEVICE FOR VEHICLE END-GATES.** JAMES W. HIRD, Benton, Wis. Filed Apr. 3, 1905. Serial No. 253,715.

Claim.—The herein-described fastening for vehicle end-gates, consisting of an end-gate hinged at its lower end and enlarged at its upper end, said end-gate having apertures at opposite sides near its upper end, a bolt mounted to revolve in keepers upon each side of the vehicle-body, said bolts each having a laterally-projecting head formed on its outer end and adapted to pass through the apertures in the end-gate when turned in one position, and a lever secured to the ends of each of said bolts for rotating the same and turning the laterally-projecting head to the position to lock the end-gate against said head, substantially as described.



812,342. **COW, CALF, AND COLT WEANER.** WILLIAM T. HORNE, Hillsboro, Tex. Filed Aug. 17, 1905. Serial No. 274,083.



Claim.—1. A weaner, provided with nostril-engaging prongs made hollow and having stiffening members inserted therein.

2. A weaner, having nostril-engaging prongs made hollow and perforated laterally, and having stiffening-tubes also perforated and adapted to contain medicinal or other remedial agents or the like.

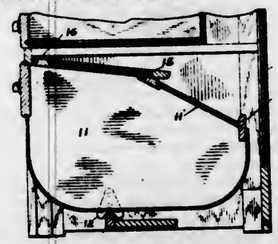
3. A weaner, having nostril-engaging prongs made hollow and provided with stiffening members, and means to hold such stiffening members in place.

4. A weaner, having nostril-engaging prongs made hollow and provided with stiffening members, and a bow-spring engaging said prongs and adapted to retain the stiffening members in place.

5. A weaner, having nostril-engaging prongs made hollow and having stiffening members inserted therein, and a lower detachable and renewable portion.

6. A weaner, having a nostril-engaging portion of soft rubber provided with hollow prongs containing stiffeners and a detachable lower portion of paper or other inexpensive material.

812,343. **TILTING BIN AND COVER.** WILLIAM C. HORNER, Indianapolis, Ind., assignor to Charles P. McDougall, Indianapolis, Ind. Filed Oct. 7, 1905. Serial No. 281,860.



Claim.—1. The combination, with a suitable casing, of a bin movably mounted therein and having an open top, a cover member mounted in said casing in position to cover said opening when the bin is closed, a laterally-movable pivotal connection between said cover member and casing, and a stop member carried by the bin and adapted to engage the cover to limit outward movement of the bin, for the purpose set forth.

2. The combination, with a suitable inclosing casing, of a bin pivotally mounted therein by a separable pivotal support and having an open top, a cover pivotally mounted in the casing at its forward end by means permitting lateral vertical displacement of the pivots, and a stop member carried at the rear of the bin and adapted to engage the cover member to limit outward swing of the bin.

812,344. **ADJUSTABLE SUPPORT.** BENJAMIN H. HOWARD, Mount Eden, Ky. Filed July 9, 1904. Serial No. 215,906.

Claim.—1. An adjustable support comprising in combination, a horizontal member consisting of a tubular member A, and a rod B longitudinally adjustable therewithin, legs comprising perforated tubular lengths and rod-like lengths slidably embraced therein, pins in said perforations limiting the relative movements of said perforated lengths with said rod-like lengths, clamping-T's provided one for each of said legs and permanently attached thereto and individually and revolubly uniting each of said legs to said horizontal member and adjustable along the latter, whereby the legs may be independently positioned along said horizontal member and angularly adjusted thereto, braces joining the lower ends of each pair of legs together and detachably affixed to one leg and pivotally affixed to the other, stiffening members diagonally connecting the lower end of each leg with the body of the horizontal member, casters upon the ends of said legs, and a middle extensible supporting member adjustably affixed to the aforesaid horizontal member, substantially as described.

2. In a paper-hanger's support, an imperforate, horizontal extensible member comprising a socketed means, and a rod slidably connected thereto within said socket, in combination with a plurality of independent extensible supporting means slidably and revolubly adjustable thereto, each comprising tube-like members having perforations extending therethrough and rod-like members capable of longitudinal movement within said tube, means for fixing said tube and rod relatively to one another, and braces connecting said horizontal member with the supporting member.

3. An adjustable support comprising in combination, a horizontal bridge member consisting of an imperforate tubular member, and a rod longitudinally adjustable therewithin, legs comprising perforated tubular lengths and imperforate rod-like lengths slidably embraced therein, pins in said perforations limiting the movement of said imperforate lengths into said perforated lengths, single clamping-T's uniting each of said legs to said horizontal member and revolubly and slidably adjustable along the latter, braces joining the lower ends of each pair of legs together, said braces being each detachably affixed to one leg and pivotally affixed to the other, stiffening members diagonally connecting by clamping-collars the lower end of each leg with the body of the horizontal member, casters upon the ends of said legs, and a middle extensible supporting member adjustably affixed to the aforesaid horizontal member, substantially as described.

4. A trestle comprising an extensible bridge-bar consisting of an imperforate tubular member and a rod telescopically engaged within same, extensible legs for supporting said bridge-bar, said legs consisting each of a single pipe-T, a thumb-screw engaging through a threaded perforation in the top part of each said T whereby same may be clamped at will at predetermined positions along said bridge-bar in diverse angular relationship thereto, imperforate rods affixed within the short leg of each said T, a perforate tubular leg member telescopically inclosing the free end of said rod, a pin adapted to be inserted through any one of said perforations whereby the insertion of said rod into said tubular member may be checked without pre-

venting the complete withdrawal therefrom, casters mounted upon the lower ends of said tubular members, braces portably but detachably affixed to one such tubular member but having the other end in connection therewith, a spur-wheel engaging said second spur-wheel being fixedly mounted upon said counter-shaft, the whole being so arranged that the double-clutch member may be shifted out

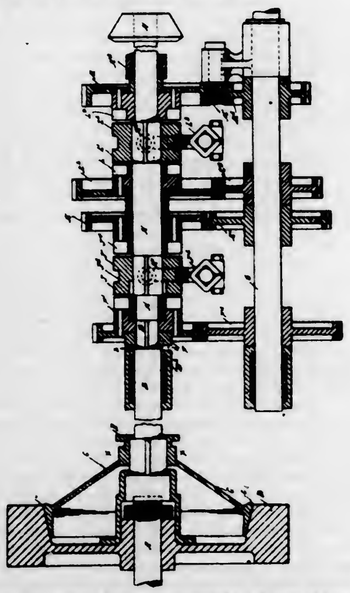
lar upper track-rail circular in cross-section, a tubular lower track-rail of an inverted-U shape in cross-section, a supporting-bracket

walls of the pulley-frame, the inner end of said upper portion having a pivot-eye, the pulley-frame having pivot-eyes on its inner walls, and

venting the complete withdrawal therefrom, casters mounted upon the lower ends of said tubular members, braces portably but detachably affixed to one such tubular member but having the other end hook-shaped for ready detachable engagement to another tubular member whereby the lower ends of each pair of legs may be positively positioned relative to one another, stiffening members extending diagonally from the lower end of each leg to points intermediate the ends of said bridge member, clamping-collars uniting the ends of said members to the adjacent trestle portions, and an extensible supporting-leg joined to an intermediate portion of said bridge-bar, substantially as described.

5. In a trestle, the combination of the legs comprising the lower sections, the vertically-adjustable upper legs comprising the upper sections and adapted to be embraced within the lower sections, suitable means for limiting the downward movement of said upper section, an elongated hook device for connecting said lower sections and preventing the latter from spreading, said device being detachably connected to one leg and permanently but pivotally affixed to the other, single T's uniting the upper end of each leg to the horizontal bar, said T's carrying each thumb-clamps for immovably affixing same, whereby each leg may be independently positioned in diverse angular and lateral relationship to said horizontal bar, a horizontal, extensible, compound bar, the same comprising a tubular member and a rod-like member telescopically arranged in said tubular member, diagonally-arranged braces pivotally connected at each end to collars embracing said legs and said horizontal bar respectively and a middle extensible support, substantially as described.

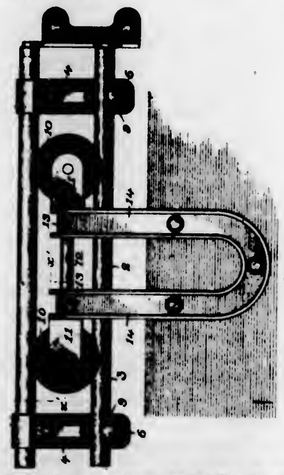
812,345. **TRANSMISSION-GEARING.** EMIL HUBER, Detroit, Mich. Filed Nov. 15, 1905. Serial No. 131,475.



Claim.—1. A change-speed gear consisting of a combination of a driving-shaft, a driven shaft, means for connecting and disconnecting said shafts, a spur-wheel and a clutch member fixed upon said driven shaft a counter-shaft, a spur-wheel upon said counter-shaft in constant engagement with the first-mentioned spur-wheel, whereby said counter-shaft is driven, a secondary shaft continuing in line with said driven shaft, a clutch member slidably engaging but rotatably fixed thereon and adapted to engage the clutch member upon the driven shaft, said clutch member being fashioned and engaging substantially as hereinbefore described, whereby the driving-shaft is enabled to drive the driven shaft with the same speed, a spur-wheel normally rotating freely upon said secondary shaft, the clutch member engaging said secondary shaft being made with an opposite clutch-section adapted to engage the spur-wheel normally rotating freely upon said secondary shaft and compelling said spur-wheel to rotate in connection therewith, a spur-wheel engaging said second spur-wheel being fixedly mounted upon said counter-shaft, the whole being so arranged that the double clutch member may be shifted centrally out of engagement with the two opposite clutch members, detaching the secondary shaft from the counter-shaft, or into engagement with the clutch member upon the spur-wheel running loosely upon the secondary shaft whereby the said spur-wheel through the intervention of the gearing upon the counter-shaft will drive said secondary shaft with a speed proportional to the gearing, gear-wheels K^3 and M normally rotating freely upon said secondary shaft, a second pair of companion clutch members upon the last-mentioned gear-wheels normally rotating freely on the secondary shaft, a second similar pair of clutch members mounted between said companion clutch members and gear-wheels and adapted to engage either one or be adjusted centrally out of engagement with both companion clutch members, gear-wheels on the counter-shaft adapted to engage the last-mentioned gear-wheels and means for shifting the last-named pair of clutch members, substantially as described.

2. The combination of a driven shaft, a gear-wheel and a clutch member fixed on said driven shaft, a counter-shaft, a gear-wheel fixed on said counter-shaft and meshing with the gear-wheel on the driven shaft, a secondary shaft in line with the driven shaft, a gear-wheel K and clutch member J^4 normally rotatable on said secondary shaft, clutch member adapted to engage the secondary shaft with the driven shaft and to unite the gear-wheel K with the secondary shaft, a gear-wheel K′ on the counter-shaft meshing with the gear-wheel K, a gear-wheel K^2 normally rotatable on the secondary shaft, a gear-wheel K^3 fixed upon the counter-shaft and engaging with the gear-wheel K^2, a gear-wheel M on the secondary shaft normally rotatable thereon, a gear-wheel upon the counter-shaft connected with the gear-wheel M, clutch members located between the gear-wheels K^2 and M and adapted to connect one or the other of the gear-wheels K^2 or M with the secondary shaft.

812,346. **DOOR-HANGER.** JOHN H. LAWRENCE, Sterling, Ill., assignor of one-half to Edwin F. Lawrence, Sterling, Ill. Filed Feb. 2, 1905. Serial No. 243,733.



Claim.—1. In a hanger for doors and the like, the combination of upper and lower stationary track-rails, brackets for supporting said rails in separated relation, a frame located between said track-rails, and means for movably connecting the frame and rails together, said frame having supporting connection with a door or the like, substantially as set forth.

2. In a hanger for doors and the like, the combination of an upper track-rail, a tubular lower track-rail of an inverted-U shape in cross-section, a supporting-bracket having upper and lower lateral arms carrying said rails, the lower arm having a receiving-socket for the base of the lower rail, a frame located between said track-rails, and means for movably connecting the frame and rails together, said frame having supporting connection with a door or the like, substantially as set forth.

3. In a hanger for doors and the like, the combination of a tubular upper track-rail circular in cross-section, a tubular lower track-rail of an inverted-U shape in cross-section, a supporting-bracket having upper and lower lateral arms carrying said rails, the upper arm having a semicircular socket and a longitudinal tongue at its outer end for engagement with the upper track-rail, the lower arm having a receiving-socket for the base of the lower track-rail, a frame located between said track-rails, means for movably connecting the frame and rails together, and said frame having supporting connection with a door or the like, substantially as set forth.

4. In a hanger for doors and the like, the combination of an upper and lower track-rail arranged in separated relation, supporting-brackets for said track-rails, a pair of flanged track-wheels confined between said track-rails, yokes in which said track-wheels are mounted, a horizontal bar connecting said yokes, and a suspension member pivotally connected to said bar, substantially as set forth.

5. In a hanger for doors and the like, the combination of a tubular track-rail of an inverted-U shape in cross-section, and a bracket having a lateral supporting-arm formed with a receiving-socket for the base of said track-rail, substantially as set forth.

6. In a hanger for doors and the like, the combination of a tubular track-rail of an inverted-U shape in cross-section, and a bracket-arm having a lateral arm provided with a pair of parallel ribs in separated relation to form a receiving-socket for the base of said track, substantially as set forth.

812,347. **DOOR-HANGER.** JOHN H. LAWRENCE, Sterling, Ill., assignor of one-half to Edwin F. Lawrence, Sterling, Ill. Filed July 31, 1905. Serial No. 271,220.

Claim.—1. A door-hanger comprising a track, a frame having vertical walls and pivot-eyes upon its inner wall, a hanger-strap adapted to be attached to a door and provided with an angular upper portion extending through the vertical walls of the frame and a pivot-eye located at the inner end of the said upper portion, and a pivot-rod connecting the pivot-eyes of the strap and the frame together; substantially as set forth.

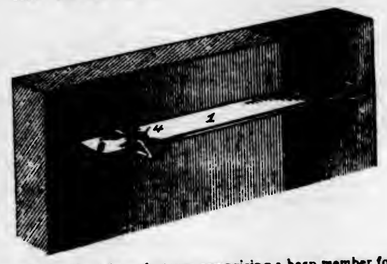
2. A door-hanger comprising a frame provided with an opening in its vertical walls, means for effecting a sliding engagement between said frame and a track-rail, a hanger-strap adapted for attachment to a door and provided with an angular upper portion adapted to pass through the opening in the vertical walls of the frame, the inner end of said upper portion having a pivot-eye, the frame having pivot-eyes on its inner wall, and a pivot-rod connecting the pivot-eyes of the strap and frame together, substantially as set forth

3. A door-hanger comprising a frame provided with an opening in its vertical walls and with a ledge or flange at the bottom of the opening in the front wall of the frame, means for effecting a sliding engagement between said frame and a track-rail, a hanger-strap adapted for attachment to a door and provided with an angular upper portion adapted to pass through the opening in the vertical walls of the frame, the inner end of said upper portion having a pivot-eye, the frame having pivot-eyes on its inner wall, and a pivot-rod connecting the pivot-eyes of the strap and frame together, substantially as set forth.

4. A door-hanger comprising a pulley-frame provided with a central opening in its vertical walls, a pair of track-pulleys journaled in said frame at the sides of said opening, a hanger-strap adapted for attachment to a door and provided with an angular upper portion adapted to pass through the opening in the vertical walls of the pulley-frame, the inner end of said upper portion having a pivot-eye, the pulley-frame having pivot-eyes on its inner wall, and a pivot-rod connecting the pivot-eyes of the strap and pulley-frame together, substantially as set forth.

5. A door-hanger comprising a pulley-frame provided with a central opening in its vertical walls and with a ledge or flange at the bottom of the opening in the front wall of the frame, a pair of track-pulleys journaled in said frame at the sides of said opening, a hanger-strap adapted for attachment to a door and provided with an angular upper portion adapted to pass through the opening in the vertical walls of the pulley-frame, the inner end of said upper portion having a pivot-eye, the pulley-frame having pivot-eyes on its inner walls, and a pivot-rod connecting the pivot-eyes of the strap and pulley-frame together, substantially as set forth.

812,348. **HASP-FASTENER.** JOHN H. LAWRENCE, Sterling, Ill., assignor of one-half to Edwin F. Lawrence, Sterling, Ill. Filed Sept. 5, 1905. Serial No. 276,231.



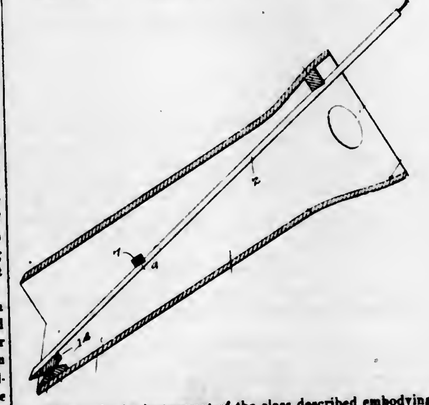
Claim.—1. A hasp-fastener comprising a hasp member formed at one end with a downturned angular extension and near the other end with a series of integral bars to form a transverse pivot-eye, substantially as set forth.

2. A hasp-fastener comprising a hasp member formed at one end with a downturned angular extension and near the other end with a series of integral bars bent in opposite directions alternately to form a transverse pivot-eye, substantially as set forth.

3. A hasp-fastener comprising a hasp member formed at one end with a downturned angular extension and near the other end with a series of integral bars bent to form a transverse pivot-eye, the end of the hasp member having an extension beyond said pivot-eye to constitute a stop for said member in its thrown-up position, substantially as set forth.

4. A hasp-fastener comprising a hasp member formed at one end with a downturned angular extension and near the other end with a series of integral bars bent in opposite directions alternately to form a transverse pivot-eye the end of the hasp member having an extension beyond said pivot-eye to constitute a stop for said member in its thrown-up position, substantially as set forth.

812,349. **OBSTETRICAL INSTRUMENT.** FRANK LEDGERWOOD, Greenfield, Iowa. Filed Oct. 27, 1905. Serial No. 284,736.



Claim.—1. An instrument of the class described embodying a tube having at one end a gripping member, a fulcrum arranged in the tube, and a lever adapted to engage with the fulcrum and provided at one end with a gripping member to coact with that of the tube.

2. An instrument of the class described comprising a tube provided at one end with a lip, a lug combined with the inner face of the lip and constituting a gripping member, a fulcrum arranged within the tube, a lever adapted to engage the fulcrum and provided at one end with a lug constituting a gripping member to coact with that of

the lip, and means for locking the two gripping members in operative relation to each other.

3. An instrument of the class described comprising a tube pro-

2. A device of the class described comprising an oil-receptacle, a shaft, and a tube communicating with the receptacle and deliver-

its end portions of different diameters, the bushing being provided with an annular passage 5 and longitudinal passage 7, and the lining having annular passage 4 in communication with passage 5 and

upper section, brushes extending therefrom and engaging the clamping-rings, and lamp-supporting wires wound on the drum and electrically connected to the collecting-ring.

the lip, and means for locking the two gripping members in operative relation to each other.

3. An instrument of the class described comprising a tube provided at one end with a lip carrying a rounded gripping member, and at its other end an abutment provided with a seat, a fulcrum disposed intermediate of the ends of the tube and provided on its under side with a seat, a lever adapted to engage the seats of the fulcrum and the abutment and provided at one end with a rounded gripping member to coact with that of the tube, and means for holding the lever in locked engagement with the abutment.

4. An instrument of the class described comprising a tube provided at one end with a gripping member and at its other end with an abutment provided with a seat and with finger-holds, a lever adapted to engage the seats of the fulcrum and abutment and having stops to coact therewith to prevent longitudinal movement, a rounded gripping member carried by the lever and adapted to coact with that of the tube, and means for locking the lever in the seat of the abutment.

5. An instrument of the class described comprising a tube provided at one end with a rounded gripping member, an adjustable fulcrum combined with the tube, and a lever adapted to coact with the fulcrum and provided at one end with a rounded gripping member to coact with that of the tube.

6. An instrument of the class described comprising a tube provided at one end with a gripping member, a fulcrum arranged in the tube, and a lever adapted to engage the fulcrum and provided at one end with a gripping member to coact with that of the tube and at its other end with hooks.

7. An instrument of the class described comprising a tube provided at one end with a gripping member, a fulcrum arranged in the tube, and a lever adapted to engage the fulcrum and provided at one end with a gripping member to coact with that of the tube and at its other end with hooks, the opposed faces of the gripping members and the hooks, being covered by yielding material.

812,350. METHOD OF STRAIGHTENING WOODEN HANDLES. JAMES W. MAXEY, Louisville, Ky. Filed Feb. 21, 1905. Serial No. 246,703.

Claim.—The method of straightening crooked handles of white hickory or similar wood which discolors if steamed or loses elasticity if soaked in hot water too long, which consists in soaking them in substantially boiling water for a time less than that which discolors them, substantially as specified, and then straightening the handles into proper shape.

812,351. TOBACCO-PIPE. JOHN MOLONEY, Miller's Forest, New South Wales, Australia. Filed Nov. 21, 1905. Serial No. 288,405.

Claim.—A pipe having a vertical chamber parallel with the bowl of the pipe, a hollow tapered separator-plug closing said chamber at the top, said plug having holes therein, some of said holes being in line with the bore in the stem of the pipe, said chamber having a small depression at its bottom, a passage leading from the bowl to the chamber, a passage in line with the first-mentioned passage, connecting the chamber with the exterior of the pipe and a plug closing said last-named passage.

812,352. LUBRICATION-PIPE. JOHANN MÜHLRAD, Jasło, Austria-Hungary. Filed May 24, 1905. Serial No. 262,103.

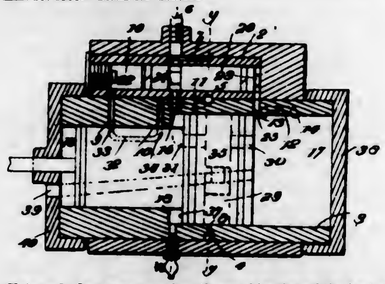
Claim.—1. A device of the class described comprising an oil-receptacle, a shaft, and vacuum-controlled means communicating with the receptacle and delivering to the shaft whereby a flow of the lubricant is effected in proportion to the speed of the shaft.

2. A device of the class described comprising an oil-receptacle, a shaft, and a tube communicating with the receptacle and delivering to the shaft said tube being restricted at its receiving end whereby a flow of the lubricant is effected in proportion to the speed of the shaft.

3. A device of the class described comprising an oil-receptacle, a shaft, a tube projecting into a vacuum-chamber communicating with the shaft and closed to the receptacle, said tube communicating at its opposite end with the receptacle and having said outer end contracted.

4. A device of the class described comprising a bearing-box provided with an oil-receptacle, a shaft, a tube projecting into a vacuum-chamber formed in said box, said chamber being closed to said receptacle and open to said shaft, said tube having a contracted inlet and being bent to bring said inlet in close proximity to the lower wall of said receptacle.

812,353. STEAM-ENGINE. JOSEPH F. MURPHY, Beals, Tex. Filed Mar. 20, 1905. Serial No. 251,026.



Claim.—1. In a steam-engine, the combination of the body provided with a working cylinder and a valve-chamber and having communicating passages, a piston arranged to operate in said cylinder and adapted to control certain passages and having a transverse opening and longitudinal openings intersecting said transverse opening, a valve mounted to slide in the transverse opening of the piston for controlling the longitudinal passages thereof and actuated at each end of the stroke of the piston by steam-pressure, and a valve mounted in the valve-chamber and moved therein by pressure of the steam controlled by the said piston.

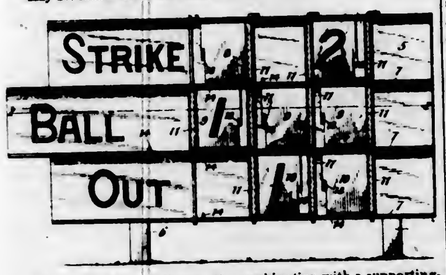
2. In an engine, the combination of a cylinder provided with passages for admission of the steam or motive medium, a piston mounted in said cylinder and provided with corresponding passages, the one providing an outlet for the exhaust or spent steam and the other admitting the steam from one side of the piston to the other for operation by low pressure, said piston having a transverse opening intersecting the passages formed therein, a valve mounted in the transverse opening of the piston and positively actuated in each direction by pressure of the steam, and means for supplying steam or like motive medium to the cylinder for driving the piston.

3. In an engine of the type described, the combination of a cylinder having opposite end portions of different diameters and having a valve-chamber and provided with steam-passages, a piston mounted in the cylinder and comprising parts of different diameters corresponding to the end portions of the cylinder, the smaller portion of the piston having a passage to establish communication between one end of the valve-chamber and the steam-supply when the piston is at the limit of its stroke in one direction, and a valve transversely mounted in the piston and adapted to control passages thereof and positively actuated by direct steam-pressure.

4. In combination, an engine-cylinder and valve-chamber in communication by means of openings 9, 15 and 25 and having steam-passages 4, 11, 10, 5, 7 and 12, and having opening 8, a piston arranged in the cylinder and provided with a transverse opening and passages 30, 32 and 28, the passage 32 adapted to register with the openings 9 and 10 when the piston is at the limit of its stroke in one direction, a valve slidably mounted in the transverse opening of the piston, and a valve mounted in the aforesaid valve-chamber and adapted to be moved by direct steam-pressure controlled by the action of the piston.

5. A steam-engine comprising a body having openings corresponding to the cylinder and valve-chamber, a bushing fitted into the smaller opening and substituting the valve-chamber, a lining fitted in the larger opening and forming the working cylinder and having its end portions of different diameters, the bushing being provided with an annular passage 5 and longitudinal passage 7, and the lining having annular passage 4 in communication with passage 5 and formed with openings 8, 9, 10, 15 and 25 and with passage 12, a valve slidably mounted in the valve-chamber and having a portion between its ends reduced to form the passage 24, a piston having its end portions of different diameters and arranged to operate in the respective end portions of the cylinder and provided with passage 32, transverse opening 29 and passages 28 and 30 intersecting the transverse opening 29, and a valve mounted in the opening 29 and having a part between its ends reduced to form passage 36, the several parts being arranged to operate substantially in the manner set forth.

812,354. INDICATOR. JOHN P. MURPHY, Sacramento, Cal. Filed May 27, 1905. Serial No. 262,673.



Claim.—1. In an indicator, the combination with a supporting-plate, of spaced flanges located on the same, said plate having an index designation disposed between the flanges, swinging flaps arranged between the flanges and having indicating-symbols that are exposed when the flaps are turned in a predetermined direction, and hinge-pintles for said flaps engaged with the said flanges.

2. In an indicator, the combination with a support having a plurality of index designations thereon, of a plurality of series of single swinging flaps, each series being in line with one of the index designations, and common hinge-pintles for securing flaps of the different series to the support.

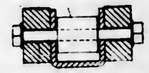
3. In an indicator, the combination with a supporting-plate, of spaced horizontally-disposed flanges located on the same, said plate having index designations located between the flanges, lines of flaps movably mounted between the flanges, and hinge-pintles passing through the flanges and constituting pivotal supports for the flaps, one face of each flap having an indicating-symbol and each of said flaps swinging to a position over the adjacent flap when swung in one direction and exposing the symbol carried thereby.

812,355. INCANDESCENT-LIGHT HANGER. ROBERT D. McINTYRE, Mansfield, Ohio, assignor of one-half to Sherman Harter, Mansfield, Ohio. Filed Mar. 6, 1905. Serial No. 248,062.

Claim.—1. In a device of the class described, a casing formed of upper and lower sections, means for connecting the sections to each other, spring-arms carried by the upper section at points outside the section and having spindle-receiving openings, a spring winding-drum having a spindle extending through said openings, collecting-rings carried by the drum, conductors arranged within the upper section, brushes extending therefrom and engaging the clamping-rings, and lamp-supporting wires wound on the drum and electrically connected to the collecting-ring.

2. In a device of the class specified, a two-part shell or casing, each member having an insulating-collar for the passage of current-conducting wires, spring-catches for holding the two members of the casing together, a spring-strip extending over the upper part of the casing and forming at its upper end a hanger or support, the lower portion of the strip being provided with spindle-receiving openings, a winding-drum having a spindle extending through said openings and provided with an insulating-cover, collecting-rings carried by the winding-drum, current-conductors arranged within the upper portion of the casing and connected to the leading-in wires, brushes carried by the current-conductors and engaging the current-collecting rings, current-conducting wires passing out through the insulating-collar of the lower part of the casing and forming a lamp-support, the upper ends of said wires being wound upon the drum and connected to the collecting-rings, and a spring for winding said drum.

812,356. LIFTING APPARATUS. JACOB NEUBAUER, Wells, Minn. Filed June 26, 1905. Serial No. 266,963.



Claim.—1. An apparatus of the class described comprising a frame consisting of parallel pairs of uprights, a brace-rod hinged to the upper end of one upright of each pair, a horizontal shaft journaled in the upper ends of said uprights, a winding-cable carried by said shaft, and means for turning said shaft.

2. An apparatus of the class described consisting of two pairs of uprights mounted upon wheels, a horizontal shaft journaled in the upper ends of said uprights, a downwardly-depending winding-cable carried by said shaft, a sprocket-chain supported upon one of said uprights and operatively connected with said shaft, an actuating-handle for said chain, and a brake supported upon said upright and engaging with said chain.

3. An apparatus of the class described consisting of two pairs of uprights mounted upon wheels and interspaced to form an intermediate driveway, cross-bars connecting the lower ends of each pair of uprights, a horizontal shaft journaled in the upper ends of said uprights, a sprocket carried by one end of said shaft, a chain connecting said sprocket with a sprocket supported upon the lower end of one of said uprights, actuating means for said chain, and a brake for said chain pivotally supported upon the adjacent upright.

4. An apparatus of the class described consisting of two pairs of uprights mounted upon wheels and interspaced to form an intermediate driveway, cross-bars connecting the lower ends of each pair of uprights, a horizontal shaft journaled in the upper ends of said uprights, a sprocket carried by one end of said shaft, a chain connecting said sprocket with a sprocket supported upon the lower end of one of said uprights, actuating means for said chain, a brake for said chain pivotally supported upon the adjacent upright, and a tightener for said chain slidably supported upon said upright.

812,357. DRY METHOD OF PREPARING LEAD COMPOUNDS. JOHN P. NEVILLE, Oakland, Cal. Filed Aug. 29, 1905. Serial No. 276,246.

Claim.—1. The dry method of preparing white lead, red lead and litharge for commercial use which consists in subjecting the material to be treated to the action of a pulverizer to reduce it into a powder, withdrawing by air-suction the powder from within the pulverizer, and discharging the dust-laden air into an arrester wherein the heavier particles of carbonate of lead separate by gravity from the laden air.

2. The dry method of preparing white lead, red lead and litharge for commercial use, which consists in converting the material to be treated into a powder, withdrawing the powdered material by air-suction, discharging the dust-laden air into an arrester wherein the heavier particles of lead separate by gravity from the laden air, and finally discharging the air from the arrester into a collector to free the air of any particles of carbonate of lead carried thereby.

3. The dry method of preparing carbonate of lead for commercial use, the same consisting in reducing the material to be treated into a powder, withdrawing by air-suction the powdered material, discharging the dust-laden air into a suitable collector for separating the lead particles from the dust-laden air and impregnating the

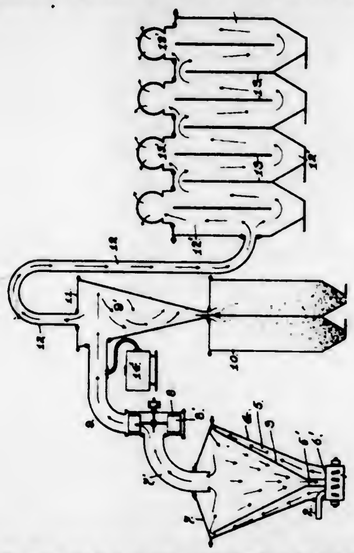
flowing body of dust-laden air with a gas, such as ozone, to oxidize and eliminate all foreign substances and such acetate of lead as may

duced end, and a locking-bar pivoted to one of said members and arranged for connection with one of the straps, said locking-bar se-

of closed and open positions so as to contact said swinging bottom-

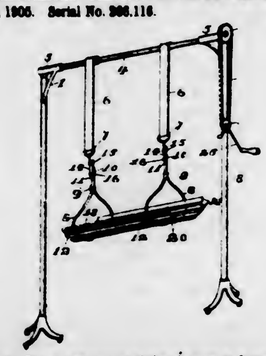
otally secured to said vibratable mechanisms and rock-shaft, and a

flowing body of dust-laden air with a gas, such as ozone, to oxidize and eliminate all foreign substances and such acetate of lead as may be contained in the powdered carbonate carried by the body of air.



4. The dry method of preparing carbonate of lead for commercial use, which consists in reducing the material to be treated to a powder, withdrawing the powder thus formed by a flowing body of air, and impregnating the flowing body of dust-laden air with a gas—such as ozone—to oxidize and eliminate all foreign substance and oxidize such acetate of lead as may be contained in the powdered carbonate carried by the body of air, and finally separating the dust-laden air of the particles of lead carbonate held therein.

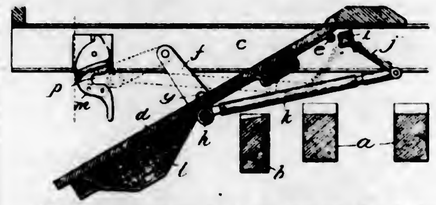
812,358. APPARATUS FOR USE IN HOSPITALS, SICK-ROOMS, AND LIKE PLACES. FREDERICK M. OLIVER, Pendleton, Oreg. Filed June 20, 1905. Serial No. 266,116.



Claim.—1. In an apparatus of the character described comprising a framework including a revoluble shaft, means for revolving said shaft, means for locking said shaft against movement in one direction, straps connected with said shaft, frame-carrying tongs connected with said straps, each of said tongs including two members pivotally connected, each of said members being formed with a reduced end, and a locking-bar pivoted to one of said members and arranged for connection with the strap.

2. In an apparatus of the character described comprising a framework including a revoluble shaft, means for revolving said shaft, means for locking said shaft against movement in one direction, straps connected with said shaft, frame-carrying tongs connected with said straps, each of said tongs including two members pivotally connected, each of said members being formed with a reduced end, and a locking-bar pivoted to one of said members and arranged for connection with one of the straps, said locking-bar securing the members in closed position when supported by the strap.

812,359. DUMP-CAR. SPENCER OTIS, Chicago, Ill., assignor to National Coal Dump Car Company, Rapid City, S. D., a Corporation of South Dakota. Filed Feb. 8, 1904. Serial No. 192,635.



Claim.—1. In a dump-car of the class described, the combination of a supporting-framework, a drop-bottom therefor formed of a plurality of swinging sections pivotally secured at their inner edges to the framework of the car at each side of the longitudinal center thereof, compound-lever mechanism pivotally secured to the framework of the car and adapted to swing and hold the swinging sections in closed position, pivoted latch mechanism for locking and holding the lever mechanism and thereby the swinging sections of the drop-bottom in closed position, and means for operating the said compound-lever mechanism, substantially as described.

2. In a dump-car of the class described, the combination of a supporting-framework, a drop-bottom therefor formed of a plurality of swinging sections pivotally secured at their inner edges to the framework of the car and at each side of the longitudinal center thereof, vibratable lever mechanism pivotally secured to the framework of the car to close said drop-bottom sections, pivoted latch mechanism for holding said vibratable lever mechanism and thereby the drop-bottom sections in closed position, and lever mechanism pivotally connected with said vibratable lever for vibrating the same, substantially as described.

3. In a dump-car of the class described, the combination of a supporting-framework, a drop-bottom portion formed of a plurality of swinging sections pivotally secured at their inner edges to the frame portion at each side of the longitudinal center thereof, a plurality of vibratable levers pivotally secured to the framework of the car, a rod engaging said vibratable lever mechanism for swinging the same and thereby the drop-bottom sections into and out of closed position, a rock-shaft, and a connecting-rod pivotally connected with said rod and with the rock-shaft to operate said vibratable lever mechanism, substantially as described.

4. In a dump-car of the class described, the combination of a supporting-framework, a drop-bottom portion formed of a plurality of swinging sections pivotally secured at their inner edges to the frame portion at each side of the longitudinal center thereof, a plurality of vibratable levers pivotally secured to the framework of the car, a rod engaging said vibratable lever mechanism for swinging the same into and out of closed position, a rock-shaft, a connecting-rod pivotally connected with said rod and with the rock-shaft to operate said vibratable lever mechanism, and pivoted latch mechanism for holding said rod and vibratable lever mechanism and thereby the drop-bottom sections locked in closed position, substantially as described.

5. In a dump-car of the class described, the combination of a supporting-framework, a drop-bottom therefor composed of a plurality of swinging sections pivotally secured at their inner edges to the supporting-framework of the car and at each side of the longitudinal center thereof, swinging lever mechanism pivotally secured to the framework of the car, rod mechanism connecting a plurality of said swinging levers together whereby they are swung into and out of closed and open positions so as to contact said swinging bottom-sections and close or open the same, and means for swinging said rod and lever mechanisms into and out of said positions, substantially as described.

6. In a dump-car of the class described, the combination of a supporting-framework, a drop-bottom therefor composed of a plurality of swinging sections pivotally secured at their inner edges to the supporting-framework of the car and at each side of the longitudinal center thereof, a plurality of swinging lever mechanisms pivotally secured to the framework of the car, rod mechanism connected with said swinging lever mechanisms and adapted to swing therewith into and out of open and closed positions so as to open and close said swinging sections, a rock-shaft, and a connecting-rod pivotally secured to said rock-shaft and to said rod and swinging lever mechanisms so as to swing the same into and out of said positions, substantially as described.

8. In a dump-car of the class described, the combination of a supporting-framework, a drop-bottom therefor composed of a plurality of swinging sections pivotally secured at their inner edges to the supporting-framework of the car and at each side of the longitudinal center thereof, a plurality of swinging levers pivotally secured to the framework of the car and provided with mechanism at their lower ends with which they swing into and out of closed and open positions, a rock-shaft, a connecting-rod pivotally connecting said rock-shaft and swinging lever mechanisms together so as to swing the same with the rod mechanism into and out of said positions, and pivoted latch mechanism for holding said rods and swinging levers and thereby the drop-bottom sections locked in closed position, substantially as described.

9. In a dump-car of the class described, the combination of a supporting-framework, a drop-bottom portion therefor composed of a plurality of swinging sections pivotally secured at their inner edges to the supporting-framework of the car and at each side of the longitudinal center thereof, a plurality of swinging levers pivotally secured to the framework of the car and provided with slots at their lower ends, rod mechanism arranged in the slots of said swinging levers with which it is swung into and out of closed and open positions, a rock-shaft, and a connecting-rod pivotally secured to said rock-shaft and rod and swinging lever mechanism for swinging the parts into and out of said positions, substantially as described.

10. In a dump-car of the class described, the combination of a supporting-framework, a drop-bottom therefor composed of a plurality of swinging sections pivotally secured at their inner edges to the supporting-framework of the car and at each side of the longitudinal center thereof, a plurality of swinging levers pivotally secured to the framework of the car and provided with slots at their lower ends, rod mechanism arranged in the slots of said swinging levers with which it is swung into and out of closed and open positions, a rock-shaft, a connecting-rod pivotally secured to said rock-shaft and rod and swinging lever mechanism for swinging the parts into and out of operative position, and latch mechanism arranged to engage said rod and hold the same with the swinging levers and thereby the drop-bottom sections in closed positions, substantially as described.

11. A car provided with a suitable track, drop-door, in combination with a wedge member movable on said track beneath said door and a compound lever for moving said member outwardly and inwardly to close and open the door respectively, substantially as described.

12. In a dump-car, the combination of a car-frame, a dumping-door pivotally mounted therein, and door-supporting mechanism mounted in the car-frame in engagement with the door and movable transversely thereof between its longitudinal center and outer swinging edges, for supporting the door in both opened and closed positions at or outside of its longitudinal center.

13. In a dump-car of the class described, the combination of a plurality of dumping-doors forming the drop-bottom thereof and extending longitudinally of the car, a rock-shaft, and lever mechanism pivotally secured to the rock-shaft and secured to the frame of the car outside of the longitudinal center of the doors for operating said dumping-doors, substantially as described.

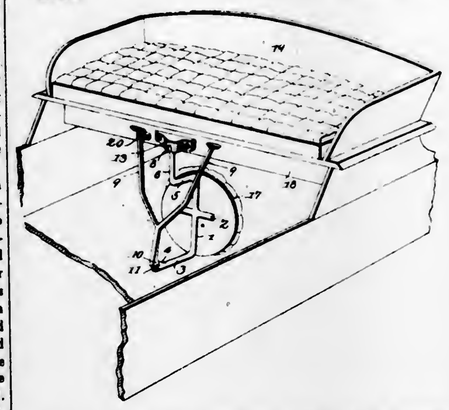
14. In a dump-car of the class described, the combination of a supporting-framework, a drop-bottom therefor composed of a plurality of swinging sections pivotally secured at their inner edges to the framework of the car at each side of the longitudinal center, a plurality of vibratable door-supporting mechanisms pivotally secured in slotted plates on the framework of the car for closing and opening said swinging sections, rod mechanism for securing a plurality of said vibratable mechanisms together and holding them against lateral displacement, a rock-shaft, a connecting-rod pivotally secured to said vibratable mechanisms and rock-shaft, and a plurality of fixed latches secured to the framework of the car for holding said vibratable mechanisms in their closed position, substantially as described.

15. In a dump-car, the combination of a car-frame, a dumping-door pivotally mounted therein, door-supporting mechanism mounted in the car-frame in engagement with the door, and movable transversely thereof between its longitudinal center and outer swinging edges for supporting the door in both opened and closed positions at or outside of its longitudinal center, and means for preventing the movement of the door-engaging portion of such supporting mechanism beyond the longitudinal center of the door.

16. In a dump-car, the combination of a car-frame, a dumping-door pivotally mounted therein, and door-supporting mechanism pivotally connected with the car-frame between the side of the car and the longitudinal center of the door and in engagement with the door between its longitudinal center and outer swinging edges when in opened position and during the movement of the door.

17. In a dump-car, the combination of a car-frame, dumping-doors pivotally mounted therein, and door-supporting mechanism connected with the car-frame between the side of the car and the longitudinal center of the dumping-doors and in engagement with such doors between their longitudinal centers and outer swinging edges in both opened and closed positions, for operating such doors and supporting them at or outside of their longitudinal centers in their open and closed positions.

812,360. AUXILIARY VEHICLE-SEAT. THOMAS W. PARKS, Alexandria, Ind., assignor of one-half to Walter B. Chenoweth, Alexandria, Ind. Filed Mar. 9, 1905. Renewed Jan. 9, 1906. Serial No. 295,302.



Claim.—1. The combination with a vehicle-seat, of a bracket secured thereto, a seat-bracket having a universal connection with the first-mentioned bracket to permit folding of the seat-bracket beneath the main seat, and a foldable prop for the seat-bracket.

2. The combination with a vehicle-seat, of a bracket secured thereto and provided with a socket intersected in its front by an upright slot and in its bottom by a horizontal slot communicating with the upright slot, a substantially horizontal seat-bracket having a ball working in the socket of the first-mentioned bracket, and a foldable prop carried by the seat-bracket.

3. An auxiliary seat for vehicles comprising a substantially horizontal seat-bracket having a pendent standard at its front end and a rearwardly-extending stem at its other end, said stem terminating in a ball, an attaching-bracket having a socket for the loose reception of the ball, and a prop member hinged to the standard of the seat-bracket.

4. The combination with a vehicle-seat, of an auxiliary seat including a seat-bracket having a universal connection with the vehicle-seat and a foldable leg-standard for the bracket, the bracket capable of being inverted and swung back beneath the vehicle-seat when the leg-standard is folded against the bracket, and means carried by the vehicle-seat for engagement with the leg-standard in the folded condition of the auxiliary seat to hold the latter against looseness.

5. The combination with a vehicle-seat, of an auxiliary seat including a seat-bracket having a universal connection with the vehicle-

seat and a foldable leg-standard for the bracket, the bracket capable of being inverted and swung back beneath the vehicle-seat when the leg-standard is folded against the bracket, and a turn-button mounted upon the vehicle-seat in position to engage the leg-standard of the auxiliary seat in the folded condition thereof to hold the same against looseness.

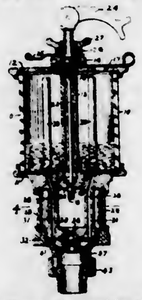
812,361. **TUBE, CONDUIT, AND PIPE CLEANER.** ALFRED PICKLES, Wakefield, and PERCY R. SEWELL, Bradford, England. Filed Oct. 8, 1903. Serial No. 176,267.

Claim.—1. In an apparatus for cleaning pipes and the like, the combination with a spindle, of a set of cutters fast to the spindle, a sleeve loosely mounted on the spindle and provided with a set of cleaning-brushes, means for rotating the spindle and means for rotating the sleeve independent of the spindle.

2. In an apparatus for cleaning pipes and the like, the combination with a spindle, of a set of cutters mounted at one end of the spindle and means for rotating the spindle mounted at the other end thereof, a sleeve loosely mounted on the spindle between the cutters and the spindle-rotating means, brushes mounted on the sleeve and means for rotating the sleeve independent of the spindle.

3. In an apparatus for cleaning pipes and the like, the combination with a series of rotary cutters mounted on a spindle a turbine also mounted on the spindle and adapted to rotate the same, a sleeve loose on the spindle, and helical plates provided with bristles clamped between them, mounted on the sleeve.

812,362. **CONSTRUCTION OF OIL-CUPS.** JAMES POWELL, Cincinnati, Ohio, assignor to The Wm. Powell Co., Cincinnati, Ohio, a Corporation of Ohio. Filed May 31, 1905. Serial No. 263,006.



Claim.—1. In an oil-cup, the combination of an oil-reservoir, consisting of a top, a bottom provided with an outlet-opening and an intervenient shell, a tie-post seated in the bottom and projecting above the top, a nut provided thereat to hold the parts of the cup together, a valve controlling the outlet, a rotary stem for actuating this valve, a pivotally-attached handle to manipulate this stem, a notched locking-arm adjustably mounted on the projecting end of the tie-post and above the nut thereon and adapted to engage the handle to hold the valve-stem against rotation and a clamping-nut also fitted on the projecting end of the tie-post above the locking-arm to hold the same in its adjusted position.

2. In an oil-cup, the combination of an oil-reservoir consisting of a top, a bottom provided with an outlet-opening and an intervenient shell, a tie-post seated in the bottom and projecting above the top with a nut provided thereat to hold the parts of the cup together, a valve controlling the outlet, a rotary stem for actuating the same, a pivotally-attached handle to manipulate this stem, a notched locking-arm adjustably mounted on the projecting end of the tie-post and above the nut thereat mentioned and adapted to engage the handle to hold the valve-stem against rotation, a spring-washer and a clamping-nut both mounted above the projecting part of the tie-post to hold the locking-arm in its adjusted position with a yielding pressure.

3. In an oil-cup, the combination of an oil-reservoir provided with an outlet-opening, a valve controlling this outlet, a rotary stem for actuating this valve, a handle pivotally attached to the upper end of this stem to manipulate the same, a locking-arm pivotally mounted and provided with serrations around its hub and with a notch in its free end adapted to engage the valve-handle to hold the valve-stem against rotation, a boss which forms the pivot for this locking-arm and has a projecting shoulder also serrated upon which the serrated part of the locking-arm rests, a spring-washer adapted to act against this serrated part of the locking-arm and means to hold the spring-washer in place.

4. In an oil-cup, the combination of an oil-reservoir and a sight-feed chamber below the same, the bottom of the former constituting also the top of the latter and dividing the two, there being a valve-controlled passage in this dividing-bottom whereby the oil-reservoir communicates with the sight-feed chamber, and a final outlet provided in the bottom of this latter and vent-ducts provided within the general structure which are open to this final outlet below the sight-feed chamber and communicating directly and independently with the interior of the oil-reservoir.

5. In an oil-cup, the combination of an oil-reservoir provided with a valve-controlled outlet, a sight-feed chamber below this outlet having a final outlet in its bottom, a check-valve controlling this final outlet and vent-ducts prorided within the general structure which communicate with this final outlet independent of the check-valve therein and open to the interior of the oil-reservoir.

6. In an oil-cup, the combination of an oil-reservoir provided with a valve-controlled outlet in its bottom, a sight-feed chamber below this bottom having a final outlet in its bottom, connecting means to hold its bottom to the bottom of the oil-reservoir, continuous perforations being provided in the two bottoms and in the means connecting them which form vent-ducts and the open ends of which communicate with the final outlet and with the oil-reservoir and tubes mounted within this latter and on the upper ends of these perforations.

7. In an oil-cup, the combination of an oil-reservoir provided with a valve-controlled outlet in its bottom, a sight-feed chamber below this bottom consisting of a shell and a bottom which has a final outlet and connecting means within and surrounded by this shell to hold the bottom of the sight-feed chamber to the under side of the bottom of this oil-reservoir with the shell mentioned clamped between the two bottoms.

8. In an oil-cup, the combination of an oil-reservoir provided with a valve-controlled outlet in its bottom, a sight-feed chamber below this bottom consisting of a shell and a bottom which has a final outlet, posts within this shell to hold the bottom of the sight-feed chamber to the under side of the bottom of the oil-reservoir with the shell mentioned held between the two bottoms, continuous perforations being provided in these two latter and in the posts connecting them which form vent-ducts and the open ends of which communicate with the final outlet and with the oil-reservoir and tubes mounted within this latter and on the upper end of these perforations.

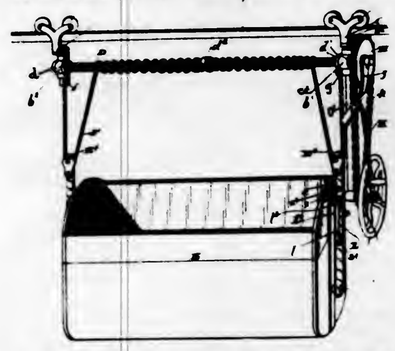
9. In an oil-cup, the combination of an oil-reservoir and a sight-feed chamber below it, both in communication by a valve-controlled passage between the two, an attaching-nipple below the sight-feed chamber, there being a passage whereby this latter communicates with the attaching-nipple, a reducing-nipple below this latter and a coupling-nut to connect the two nipples.

10. In an oil-cup, the combination of an oil-reservoir and a sight-feed chamber below it, both in communication by a valve-controlled passage between the two, an attaching-nipple below the sight-feed chamber, there being a passage whereby this latter communicates with the attaching-nipple, a check-valve controlling this passage in one direction and vent-ducts provided within the general structure whereby the attaching-nipple communicates with the interior of the oil-cup independent of the check-valve.

11. In an oil-cup, the combination of an oil-reservoir and a sight-feed chamber below it, both in communication by a valve-controlled passage between the two, an attaching-nipple below the sight-feed chamber, there being a passage provided within the general structure whereby the attaching-nipple communicates with the sight-feed chamber and independent vent-ducts whereby this latter communicates with the interior of the oil-cup.

12. In an oil-cup, the combination of an oil-reservoir and a sight-feed chamber below it, both in communication by a valve-controlled passage between the two, an attaching-nipple below the sight-feed chamber, there being passages provided within the general structure whereby this attaching-nipple communicates with the sight-feed chamber and independently with the interior of the oil-cup, a reducing-nipple below this attaching-nipple and means to connect the two nipples.

812,363. **FEED AND LITTER CARRIER.** JAMES W. PROVAN, Oshawa, Canada. Filed Apr. 1, 1904. Serial No. 201,180.



Claim.—1. In a feed and litter carrier, in combination a short depending suspension-bar and a long suspension-bar, the spindle journaled in the ends of the long and short bars, the collars on the spindle on each side of each bar, the sprocket-gear having the upper sprocket-wheel secured on the end of the spindle outside of the long bar and the lower sprocket-wheel journaled on a stud at the bottom of the long bar and the box adjustably supported on the main spindle by the cord as specified.

2. In a litter-carrier, the combination with the bars and wheels, and a spindle journaled on the bars, of the box, the hanger pivotally connected to the end of the box and provided with forked upper ends carrying pulleys, the cord secured to the eyes on the bars and passing under the pulleys at the top of the hangers of the box and fastened to the spindle as and for the purpose specified.

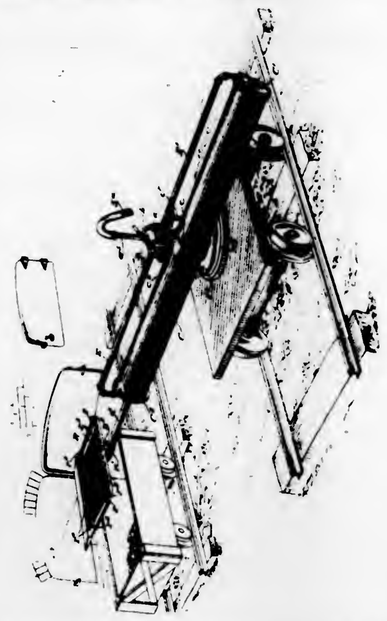
3. The combination with the box and hangers pivotally connected to the end of the box, the spindle, and bars in which the same is journaled and means for supporting the hangers from the spindle, of a bar secured in the end of the box and provided with a notch, and means for throwing the box away from the hanger, so as to release such hanger from the notch as and for the purpose specified.

4. The combination with the box and hanger pivotally connected to the end of the box, the spindle, and bars in which the same is journaled and means for supporting the hangers from the spindle, of a bar secured in the end of the box and provided with a notch, a lever pivoted on the bar, and means for operating the lever, so as to throw the notched bar clear of the hanger in order to dump the box as and for the purpose specified.

812,364. **COKE-DRAWING MACHINE.** DANIEL A. RAHAGE, Percy, Pa. Filed Nov. 1, 1905. Serial No. 285,441.

Claim.—1. A coke-drawing mechanism, which comprises a wheel-frame, a cylinder axially mounted on the center thereof to turn in the horizontal plane, a frame surrounding the cylinder and having a seat to engage a stud axially on the wheeled frame, the stud-axle having a horizontally-disposed gear fixedly mounted thereon, a pinion on a shaft mounted on the annular frame on the cylinder adapted to mesh with the gear-wheel on the supporting-frame, a fluid-pressure feed, a piston working within the cylinder, a valve mechanism detachably mounted on the annular frame on the cylinder, the casing of said valve having two feed-ports, an inlet and an exhaust, a valve operating in said casing for alternately moving the opposite one of the inlets in communication with the feed-port and at the same time bringing the other feed-port into communication with the exhaust-leads from the feed-ports, one of which discharges into the rear end of the cylinder, the other one of which discharges into the front end of the cylinder, and a draw or scraping device detachably mounted on the front of the piston-rod, all being arranged substantially as shown and described.

2. A coke-drawing machine, comprising in combination, a truck-frame having a central axial stud, and a horizontal gear fixedly mounted thereon, a cylinder mounted upon the axial stud to turn in a horizontal plane, a pinion and a shaft for the same mounted on the cylinder, said pinion engaging the horizontal gear, a source of fluid-pressure, a regulating-valve mechanism mounted on the cylinder having a feed-pipe connection that discharges into one end of the cylinder, another feed-pipe connection that discharges into the other end of the cylinder, and having a feed-inlet and an exhaust, the piston within the cylinder having its rod extended and a scraper-frame connected to the front end of the piston, as set forth.



3. A coke-drawing means comprising a truck-carriage having a centrally-disposed turn-table, a cylinder mounted on said turn-table, means mounted on the cylinder for actuating the turn-table devices, a pressure-fluid lead-pipe that discharges into one end of the casing, a second pipe that discharges into the other end of the casing, a source of fluid-pressure supply, a controlling-valve mechanism mounted on the cylinder and adapted to have a flexible connection with the fluid-pressure supply, said valve also connecting with the feed-pipes to the cylinder, a lever device for setting the valve to cut out one feed-pipe as it exhausts the other, the piston and its rod, and a scraper device detachably mounted on the end of said rod as set forth.

4. In a coke-drawing mechanism of the character described, the combination with the wheeled frame, the cylinder mounted to turn in a horizontal plane, means for adjusting the cylinder, means for feeding and exhausting the fluid-pressure in the cylinder to actuate the piston, said means being carried by the cylinder, the piston and its rod and a drawing or scraper device, comprising a frame having a series of forwardly-extending bars, a spear-shaped cross member that joins the front ends of the said bars, a rib or latch pivotally secured to each of the said bars, and mounted to normally drop to a horizontal position when the scraper is inserted into the coke and to rise to a vertical position when the scraper is pulled, said scraper having guide-rolls at the rear edges, all being arranged substantially as shown and described.

5. In a coke-drawing mechanism of the character described, the combination with a wheeled frame, the cylinder mounted thereon to turn in a horizontal plane, means for adjusting the cylinder and means for feeding and exhausting a fluid-pressure of the cylinder to actuate the piston, said means being carried by the cylinder, the piston and its rod, and a drawing or scraper device mounted on the outer end of the rod which comprises a frame having a series of forwardly-extending bars, a spear-shaped cross member that joins the front end of said bars, a rib or latch pivotally secured to each of said bars and mounted to normally drop to a horizontal position when the scraper is inserted into the coke and rise to a vertical position when the scraper is pulled out, substantially as shown and described.

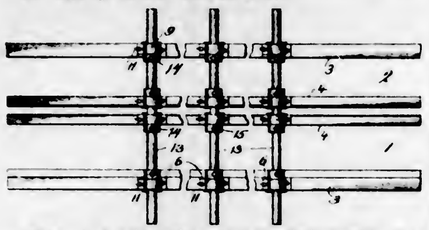
812,365. **MOLD FOR CONCRETE WALLS.** JOHN L. RICHARDSON, Bloomsburg, Pa., assignor of one-half to Fred J. Richard, Bloomsburg, Pa. Filed Apr. 19, 1905. Serial No. 256,506.

the core, and a retaining-screw passed through the outer end of the bushing and threaded longitudinally into the free end of the core.

having a pair of annular flanges disposed substantially at a right angle to each other and provided with a plurality of radial partitions

2. In an internal-combustion engine the combination of a governor-controlled air-valve; a governor-controlled liquid-fuel valve; a governor-controlled water-valve; two reservoirs for containing liq-

812,365. **MOLD FOR CONCRETE WALLS.** JOHN L. RICHARDSON, Bloomsburg, Pa., assignor of one-half to Fred J. Richard, Bloomsburg, Pa. Filed Apr. 19, 1905. Serial No. 256,506.



Claim.—1. A mold for the purpose described comprising form-plates, a rod extending transversely above said plates, and means for connecting and adjusting said plates independently of each other on said rod.

2. A mold for the purpose described comprising form-plates, a rod extending transversely above said plates, a clamp adapted to engage said rod carried by each of said plates whereby said plates are capable of independent connection with and adjustment on said rod.

3. A mold for the purpose described comprising two sets of plates assembled to form wall-sections separated by an air-space, a rod extending transversely above said plates, a clamp adapted to engage said rod carried by each of said plates whereby said plates are capable of independent connection with and adjustment on said rod.

4. A mold for the purpose described comprising form-plates, a rod extending transversely above said plates, a gage for each plate adjustably mounted on said rods, a clamp adapted to engage said rod carried by each of said plates whereby said plates may be connected to and adjusted on said rod independently of each other.

5. A mold for the purpose described comprising two sets of plates assembled to form wall-sections separated by an air-space the inner plates of said sections having their opposing faces inclined so as to converge toward each other downwardly, a correspondingly-shaped spreader adapted to be inserted into the space between said inner plates, a rod extending transversely above said plates, a clamp adapted to engage said rod carried by each of said plates whereby said plates may be connected to and adjusted on said rod independently of each other.

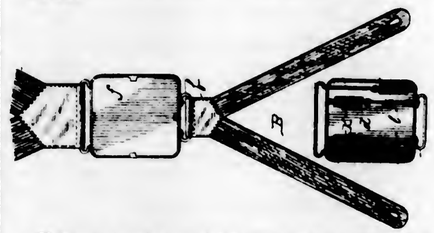
6. A mold for the purpose described comprising form-plates a rod extending transversely above said plates, means for connecting and adjusting said plates independently of each other on said rod, and a tie-rod passing through said plates to clamp them to the preceding course, said tie-rod being so disposed as to rest upon the top of said course when the parts of the mold are assembled.

812,366. **PIPE-DRESSING TOOL.** WILLIAM RITSCHARD, Columbus, Ohio. Filed Dec. 31, 1904. Serial No. 239,949.

Claim.—1. In an implement of the class described, a body, a journal-stem carried thereby and comprising a core, a bushing mounted on the core, a screw connecting the outer ends of the core and bushing to hold the same against relative longitudinal movement, the body and bushing being provided, one with a key and the other with a socket that receives the key to hold the bushing against rotary movement on the core, and a cutter carried by the body and disposed at an inclination to the core.

2. In an implement of the class described, a body having a tapering work-receiving socket, a journal-stem extending centrally within the socket, said body having a recessed key-seat at the inner end of the socket at one side of the base of the core, a cutter carried by the body and projecting into the socket, a bushing detachably fitted upon the core and having a lateral outstanding key at its inner end that fits in the socket and holds the bushing against rotation on the core, and a retaining-screw passed through the outer end of the bushing and threaded longitudinally into the free end of the core.

812,367. **ATTACHMENT FOR GARMENT-SUSPENDERS.** WILLIAM F. ROWELL, Deadwood, S. D. Filed Sept. 25, 1905. Serial No. 280,085.

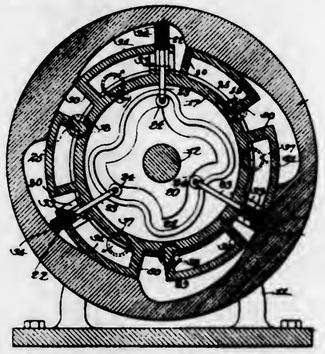


Claim.—1. A spring attachment for garment-suspenders consisting of a casing, rods working in pairs independently of each other in opposite sides of the rim of said casing; coiled contractile springs connected within said casing to said rods and casing; and bows outside of said casing connected to said rods; said parts being combined substantially as described.

2. A spring attachment for garment-suspenders having a casing with a covering-plate, bows on opposite sides of the rim of said casing, each having a pair of rods connected therewith and passing through said rim, and inner and outer pairs of springs within said shell and connected to said rods and casing, the inner springs being connected to one of said pairs of rods and the outer springs being connected to the other pair of rods, said parts being combined substantially as described.

3. An attachment for garment-suspenders consisting of a casing with a covering-plate, bows outside of opposite sides of the rim of said casing, pairs of rods passing through opposite sides of said rim, one of said pairs of rods being between the other pair, and coiled contractile springs secured to said rods and to the casing, and one of said bows being of greater width than the other bow, said parts being combined substantially as described.

812,368. **ROTARY ENGINE.** CARL A. SANDBORG, Bloomington, Ill. Filed May 8, 1905. Serial No. 259,406.

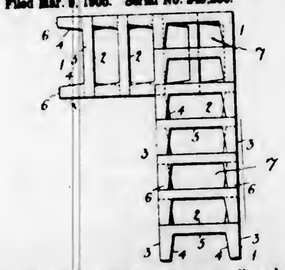


Claim.—1. The combination with a frame, of a stationary piston supported thereby, radially-slidable abutments carried by the piston, a shaft extending through said piston, a revoluble cylinder carried by the shaft and provided with steam-chambers into which the abutments may be moved, and a cam-disk carried by the cylinder for moving the abutments.

2. The combination in a rotary engine, of a frame, a stationary piston supported thereby and having peripheral pockets, a plurality of radially-movable abutments guided by the piston, a shaft, a revoluble cylinder carried by the shaft and provided with steam-chambers into which the abutments may be moved, a disk carried by the cylinder and provided with a cam-groove, and stems secured to the abutments and provided with pins or antifriction-rollers entering said cam-groove.

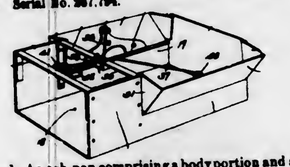
3. In a rotary engine, the combination with a stationary piston having a pair of annular flanges disposed substantially at a right angle to each other and provided with a plurality of radial partitions dividing the periphery of the piston into a series of pockets, a revoluble piston having a plurality of steam-chambers, packing-rings between the flanges of the piston and the cylinder, a disk carried by the cylinder and provided with a cam-groove, radially-movable abutments carried by the piston, guiding means for such abutments, and stems secured to such abutments and provided with pins or antifriction-rollers entering said cam-groove.

812,369. **BUILDING-BLOCK.** FRANK M. SAWYER, Charlotte, N. C. Filed Mar. 9, 1905. Serial No. 249,256.



Claim.—The herein-described building-wall made up of bricks or blocks having three unbroken surfaces 2, 3, 3, the surfaces 3, 3, forming feet 6, the inner walls 4 of which are oblique and providing the inner wall or web 5, said blocks being placed in reverse order in each alternate layer to break joint and to provide vertical ventilating-spaces 7 between the bricks and to form cross bracing-webs in the corners of the wall, essentially as described.

812,370. **ASH-PAN.** LOUIS C. SCHOTTO, St. Louis, Mo. Filed June 30, 1905. Serial No. 267,794.



Claim.—1. An ash-pan comprising a body portion and side wings, portions of the side walls of the pan-body being of reduced height, and the wings being pivoted to such portions of reduced height.

2. An ash-pan comprising a body portion and side wings, portions of the side walls of the pan-body being of reduced height, and the wings being pivoted at the top of such portions, the ends of the wings being arranged to swing within the body of the pan.

3. An ash-pan having depressions in its side walls, and wings mounted to swing within said depressions and extending inwardly to the body of the pan at the ends.

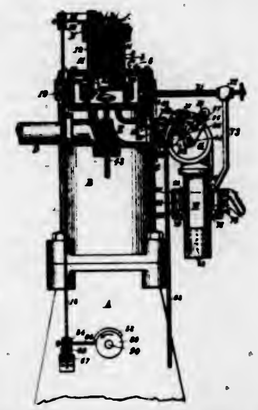
4. An ash-pan comprising a body portion and wings, portions of the side walls being of reduced height, and the wings being pivoted at the top of such portions, transverse stay-bars connecting those portions of the side walls of full height, one of said bars having a central depression, and pivotally-connected levers extending through the depressed portion of the stay and movably connected to said wings.

5. An ash-pan comprising a body and wings, portions of the side walls of the pan being of reduced height, and the wings being pivoted at the top of such portions and of such width that when moved inward their upper edges will be substantially in alinement with the upper edges of the main portion of the side walls.

812,371. **SPEED-REGULATOR FOR EXPLOSIVE-ENGINES.** JOHN A. SPROUL, New York, N. Y., assignor to General Power Company, a Corporation of New Jersey. Filed Mar. 16, 1904. Serial No. 198,345.

Claim.—1. In an internal-combustion engine the combination of an air throttling-valve, a fuel throttling-valve, and a water throttling-valve, with a governor adapted to vary the quantity of the combustible charge, and the relative proportions of air, fuel and water, in coördination with the variations in quantity of said charge.

2. In an internal-combustion engine the combination of a governor-controlled air-valve; a governor-controlled liquid-fuel valve; a governor-controlled water-valve; two reservoirs for containing liquid, each provided with means for maintaining the surface of the liquid contained therein at a constant height; a connecting-passage, or pipe from one of said reservoirs to said liquid-fuel valve; and a connecting-passage, or pipe from the other of said reservoirs to said water-valve.



3. In an internal-combustion engine the combination of an air throttling-valve, a fuel throttling-valve, a water throttling-valve, a liquid-fuel receptacle, and a water-receptacle, each of said receptacles having a discharge passage-way opening into the air-inlet passage at a level above the surface of the liquids contained in said receptacles, with a governor adapted to vary the quantity of the combustible charge, and the relative proportions of air, fuel and water, in coördination with the variations in quantity of said charge.

4. In an internal-combustion engine adapted to inhale water, the combination of a common admission-passage and valve for admitting a mixed charge of air, fuel and water, a governor adapted to control simultaneously and independently, the supply of air and fuel contained in each charge; a reservoir for holding water; a pipe, or vertical passage-way connecting with said reservoir having an inlet near the bottom of the reservoir, and an outlet in said admission-passage, with means for maintaining a constant level in said water-reservoir, said level being below the level of said outlet in said admission-passage.

5. In an internal-combustion engine having a cylinder and piston therein adapted to employ the reduced internal pressure, occurring during each suction-stroke in order to inhale water as a constituent ingredient of the fuel charge, the combination of a common admission passage and valve for admitting air, fuel and water, means for enabling said piston during said suction-stroke to inhale the air, fuel and water, with means for automatically varying in coördination the proportions of said air, fuel and water, and the volume of mixture, so as to provide relatively weaker mixtures for higher compressions and increasingly stronger mixtures for the lower compressions.

6. In an internal-combustion engine having independent air, fuel and water valves, the combination with a governor of means for enabling said governor to vary the relative proportions of air, fuel and water contained in the combustible mixture, and an ignition mechanism operatively connected with said governor for varying the time of ignition in coördination with said variation in relative proportions, substantially as, and for the purpose specified.

7. In an internal-combustion engine in which the governor controls simultaneously and independently the supply of air, fuel and water, composing the successive charges admitted to the engine, and the time of firing each charge, the combination of an air throttling-valve, a fuel throttling-valve, and a water throttling-valve, with a governor adapted to vary the quantity of the combustible charge, and the relative proportions of air, fuel and water, in coördination with the variation in quantity of said charge.

8. In an internal-combustion engine in which the governor controls simultaneously and independently, the supply of air, fuel and water composing the successive charges admitted to the engine, and the time of firing each charge, the combination of an air throttling-

valve, a fuel throttling-valve and a water throttling-valve, all operating simultaneously and independently, the supply of air and fuel contained in each charge; a fuel throttling-valve connected by, and opening into said

spaces in said pieces, buffers provided with tongues and beveled por-

to the platform, said auxiliary motors being located at points inter-

valve, a fuel throttling-valve and a water throttling-valve, all opening into a common admission-passage, or valve-chamber, and an electrical ignition-timing mechanism, with a governor, adapted to control in unison, the proportions and quantity of air, fuel and water, and the time of ignition.

9. The combination with an internal-combustion engine of a governor adapted to control in unison the relative movements of an air-valve, a fuel-valve, a water-supply device, and an electric ignition-timing device; said governor operatively controlling in common the movements of said mechanisms so as to determine (1) the relative proportions of air, fuel and water contained in each combustible charge; (2) the volume of each charge; and thereby the degree of compression of each charge; (3) the internal temperature of the combustion-chamber; (4) and the time of ignition of said combustible charge.

10. In an internal-combustion engine, the combination of a governor adapted to control an air-valve, a fuel-valve, a water-supply mechanism, and an ignition-timing mechanism, so as to alter the time of firing, and the relative proportions between the air, fuel and water, and the total quantity of said air, fuel and water entering the combustion-chamber of the engine, and thereby the compression, and temperature of each successive combustible charge in said combustion-chamber, in response to the variations in speed, or power, with means for changing the limits of rotative speed within which said governor performs said common control.

11. In an internal-combustion engine in which the governor controls simultaneously and independently, the supply of air, fuel and water composing the successive charges admitted to the engine, the combination of a liquid-fuel reservoir and a water-reservoir, each of said reservoirs connecting with a throttling-valve which has an outlet located within the air-inlet passage, and in the path of the inward air-current, an air throttling-valve, opening into said air-inlet passage, with a governor for controlling all of said valves, and a working piston adapted by its movement during the suction-stroke to inhale the air, fuel and water forming the combustible mixture simultaneously.

12. In an internal-combustion engine having a cylinder and piston therein, the combination of a liquid-fuel reservoir, a liquid-fuel throttling-valve, an air throttling-valve, a governor, and valve-operating devices connected with said governor for imparting movements to each of said throttling-valves whereby said governor varies the volume of mixture and also increases the proportion of fuel as the volume of mixture is decreased; with means for enabling said piston to inhale liquid fuel from said reservoir during the suction-stroke, the air and fuel being inhaled at the same time, temperature and pressure, and at a common place of admission, substantially as described.

13. In an internal-combustion engine adapted to inhale water for internal cooling, the combination of a piston adapted by its suction movement to inhale each ingredient of a combustible mixture at the same time, the same temperature, under the same pressure, and through the same admission-valve and also to atomize and commingle the liquid ingredients with the air-supply; a governor adapted to vary the volume of the fuel mixtures, as well as the relative proportions of the constituent ingredients in said mixtures; a combustion-chamber in which the air charge absorbs and incorporates the vapors evolved from the atomized liquids commingled with, and held in suspension by said air charge; substatially as, and for the purpose specified.

14. The combination with the admission-passage of an internal-combustion engine, of a combustion-chamber in which the vapors of the liquid ingredients of the fuel charge are evolved by heat while intermingled with the air charge, and of air, fuel and water are evolved by heat while intermingled with throttling-valves communicating with said admission-passage; and a governor having a yielding connection with two of said throttling-valves and a rigid connection with the third.

15. In an internal-combustion engine the combination, with an air-admission passage of a liquid throttling-valve consisting of a tubular body supported by, and passing across said air-admission passage and held therein by a nut or screws, having a centrally-located outlet-opening in the form of a nozzle in the path of the air through said air-admission passage; a screwed valve-stem within said body, a hollow removable seat within said body, meeting said stem at or near said outlet, and a gland or packing nut for preventing leakage about said stem.

16. In an internal-combustion engine, the combination of an admission-passage; a perforated pipe connecting said passage with the atmosphere; an admission-valve, connecting said passage with the combustion-chamber; an air throttling-valve restricting said passage; a fuel throttling-valve supported by, and opening into said passage; between said air throttling-valve and said admission-valve, having an outlet at substantially right angles to said passage, in close proximity to the restricted opening of said air throttling-valve; an inertia-governor; a yielding connection with said fuel throttling-valve; and mechanism for actuating said fuel throttling-valve by said governor through said yielding connection, so as to vary both the actual and the relative openings of said throttling-valve.

17. In an internal-combustion engine adapted to have its operation started by means of a limited, or predetermined supply of volatile liquid fuel, the surface level of which is steadily lowered, and the quantity contained in each successive charge continuously lessened, the combination of a governor-actuated air throttling-valve, a reservoir for holding the predetermined supply of volatile liquid fuel, an opening in said reservoir for filling the same, a pipe or passage-way connecting the lower part of said reservoir with the inlet-passage of said air throttling-valve, having an outlet lower than said opening for filling, but arranged so that said reservoir cannot be emptied by gravity; said outlet discharging substantially at a right angle to the path, or direction of the air-current, entering said air throttling-valve.

812,372. **LOCK-BUCKLE.** JOHN SHAW, Kirwin, Wyo. Filed Mar. 6, 1905. Serial No. 248,730.

Claim.—1. A lock-buckle comprising a frame, a tongue connected with the frame, one end of the frame having a raised transverse part and the other end of the frame being provided with a lock, and a locking-bar hinged to the rear transverse part of the frame, while its opposite extremity is provided with a part adapted to enter the lock-casing, the locking-bar occupying a position in line with the tongue of the buckle for the purpose set forth.

2. As an improved article of manufacture, a buckle comprising a frame, a tongue hinged to the pin of the frame, a raised transverse part extending upwardly from the pin, a bar hinged to the raised transverse part, a lock connected with the forward part of the buckle-frame, the said bar being provided with a part adapted to enter the casing of the lock for locking purposes.

3. In a buckle, the combination of a frame, tongue and tongue-pins, of a rear transverse part connected with the buckle-frame and located above the pin thereof, a lock connected with the forward part of the buckle-frame, and a bar hinged to the rear transverse part and having a part entering the casing of the lock for the purpose set forth.

4. The combination with a buckle-frame and its tongue, of a lock rigidly connected with one extremity of the buckle-frame, and a bar hinged to the opposite extremity of the buckle-frame and having a part adapted to enter the lock, the bar being located in line with the tongue of the buckle for the purpose set forth.

812,373. **PNEUMATIC-TIRE PROTECTOR.** LESTER L. SIDWELL, Rivera, Cal. Filed Sept. 23, 1904. Serial No. 226,661.

Claim.—1. A tire-protector comprising a series of curved protecting-pieces, buffers secured between said pieces and means for securing the said curved protecting-pieces upon the tire, said means adapted to slide upon the said curved pieces.

2. A tire-protector comprising a series of curved protecting-pieces provided with dovetailed recesses therein, buffers having dovetailed tongues adapted to be secured in said recesses and means for retaining said protecting-pieces upon the tire.

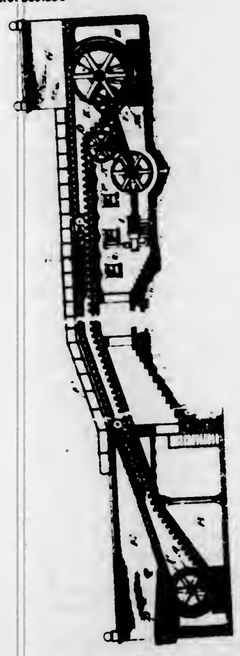
3. A tire-protector comprising curved protecting-pieces having cut-away portions in the adjoining edges thereof and dovetailed recesses in said pieces, buffers provided with tongues and beveled portions adapted to be secured between the adjacent edges of said protecting-pieces and means for retaining said protecting-pieces upon the tires.

4. A tire-protector comprising a series of curved protecting-pieces having hooks upon the ends thereof, buffers secured between said pieces, wires adapted to be seated upon the hooks and adapted to automatically slide thereon when the tire is contracted and expanded.

5. A tire-protector comprising curved protecting-pieces having hooks upon the extremities thereof and provided with grooves upon the inner faces of said pieces, buffers adapted to be secured between the adjoining edges of said protecting-pieces and means for retaining said pieces upon the tire.

6. A tire-protector comprising a series of curved protecting-pieces having hooks upon the ends thereof and provided with grooves upon the inner faces of said pieces, buffers secured between the adjacent edges of said pieces and means for securing the said pieces upon the tire.

812,374. **MOVABLE ROADWAY.** ISAAC D. SMEAD, Cincinnati, Ohio, assignor to Burton A. Smead, Cincinnati, Ohio. Filed May 24, 1904. Serial No. 209,554.



Claim.—1. In an apparatus of the character described, the combination of an endless platform; means for supporting the upper stretch of the platform throughout its length; means for supporting the lower stretch thereof; a main motor for driving the platform; and a series of auxiliary chain-motors arranged at various points in the length of the platform, said chain-motors engaging both the upper and lower stretches of the platform.

2. In an apparatus of the character described, the combination of an endless platform; a main motor for driving the same; and an auxiliary motor comprising an endless chain provided with engaging teeth or projections, said auxiliary motor being located at a point intermediate the loops or ends of the platform and engaging the upper and lower stretches thereof.

3. In an apparatus of the character described, the combination of an endless platform; means for supporting the upper stretch of the platform throughout its length; means for supporting the lower stretch thereof; a main motor for driving the platform, said motor being located adjacent to the loop or end of the platform; and a series of auxiliary chain-motors also employed for imparting motion to the platform, said auxiliary motors being located at points intermediate the loops or ends of the platform and engaging the upper and lower stretches thereof, substantially as described.

4. In an apparatus of the character described, the combination of an endless platform; a main driving-motor; a series of auxiliary driving-motors; and means for starting and stopping the various motors in unison.

5. In an apparatus of the character described, the combination of an endless platform; means carried by one face of the platform for supporting the upper stretch thereof throughout its course of travel; track mounted upon the opposite face of the platform; and a support acting in conjunction with said track to sustain the lower stretch of the platform throughout its length.

6. In an apparatus of the character described, the combination of a suitable support; an endless platform comprising a series of jointed sections; means secured to the under face of said sections for properly supporting and guiding the platform throughout the length of its upper stretch; means upon the outer face of the platform for properly supporting and guiding the lower stretch thereof during its course of travel; and a motor for driving the platform.

7. In an apparatus of the character described, the combination of a suitable support or framework; an endless platform comprising a series of sections pivotally connected together; means for driving said platform; a series of rollers S, S′ upon the inner face of the platform; tracks T, T′ mounted upon the framework in line with said rollers; tracks U, U′ likewise secured upon the inner face of the platform; a series of rollers V, V′ in line with said tracks U, U′; tracks Q, Q′ mounted upon the outer face of the platform; and rollers P, P′ in line with said last-named tracks.

8. In an apparatus of the character described, the combination of an endless platform comprising a series of sections; a series of driving members secured to said platform-sections and pivotally connected to each other; a main motor for driving said platform; and a series of auxiliary motors disposed throughout the length of the platform, said motors imparting motion to said platform through the driving members thereof.

9. In an apparatus of the character described, the combination of an endless platform comprising a series of sections; driving members secured to said platform and pivotally connected to each other; a main motor; and an auxiliary motor, said auxiliary motor comprising a sprocket-chain, one stretch of which engages with the driving members secured to the platform, and means for driving said sprocket-chain.

10. In an apparatus of the character described, the combination of an endless platform comprising a series of sections; driving members secured to said platform and pivotally connected to each other; a main motor; and an auxiliary motor, said auxiliary motor comprising a sprocket-chain, means for holding the upper stretch of said chain in engagement with the driving members, and means for imparting motion to said sprocket-chain.

11. In an apparatus of the character described, the combination of an endless platform comprising a series of sections; driving members secured to said platform and pivotally connected to each other; a main motor; and an auxiliary motor, said auxiliary motor comprising an endless sprocket-chain, means for holding the upper stretch thereof in engagement with the driving members of the platform, means for guiding the lower stretch of the sprocket-chain, and means for imparting motion to said chain.

12. In an apparatus of the character described, the combination of an endless platform comprising a series of sections; driving members secured to said platform and pivotally connected to each other; a main motor; and an auxiliary motor, said auxiliary motor comprising an endless sprocket-chain, means for holding the upper stretch thereof in engagement with the driving members of the platform, means for guiding the lower stretch of said sprocket-chain and causing the same to engage the lower stretch of the endless platform, and means for imparting motion to said chain.

812,375. **ROCK-DRILL.** CLARK J. SMITH, Ottumwa, Iowa, assignor to The Hardsog Wonder Drill Company, Ottumwa, Iowa. Filed Aug. 7, 1905. Serial No. 273,126.

Claim.—1. In an apparatus of the class described, a supporting-casing, a drilling mechanism supported therein and feedable therethrough, means coöperatively connecting the supporting-casing and the drilling mechanism to permit the drilling mechanism being fed forward at each forward impulse of the drill-hammer, and means whereby said drilling mechanism can be bodily withdrawn from said supporting-casing, substantially as shown and described.

2. In an apparatus of the class described, a drilling mechanism

including a reciprocating hammer and a longitudinal drill-casing, a

7. An apparatus of the class described, comprising a drilling mechanism consisting of a longitudinal tubular casing, having an

tion of the drill upon its longitudinal axis substantially as shown and described.

2. The combination of a door for an air-tight apartment; a door-frame comprising jambs *a*, and *b*, a lintel *c*, blocks *k*, *l*, *r*, and *q*, a

including a reciprocating hammer and a longitudinal drill-casing, a supporting-casing for receiving said drill-casing, said drill-casing having an exterior thread, means whereby said drill-casing can be rotated on its longitudinal axis to feed the same forward, means carried by said supporting-casing for coöperatively engaging the threaded portion of the drill-casing to enable it to have a threaded connection with the drill-casing, and means whereby said last-named means can be released from operative connection with the drill-casing to permit the drill-casing being drawn out of the supporting-casing, substantially as shown and described.

3. An apparatus of the class described, comprising a drill including a casing and a reciprocating hammer operable therein, said drill-casing having an externally-threaded portion, a supporting-casing having an internal bore for receiving said drill-casing, a drill-casing-engaging member on said supporting-casing for engaging said threaded portion of the drill-casing to lock the same to the supporting-casing, means carried by the drill-casing whereby the drill-casing can be turned on its longitudinal axis to feed the same, said drill-casing and said drill-casing-engaging member being so arranged as to permit the drill to be automatically fed forward on its longitudinal axis at each forward impulse of the hammer, all being arranged substantially as shown and described.

4. An apparatus of the class described, comprising a drill including a drill-casing and a reciprocating hammer operable therein, said drill-casing having an externally-threaded portion, a supporting-casing having an external bore for receiving said drill-casing, a drill-casing-engaging member on said supporting-casing for engaging said threaded portion of the drill-casing to lock the same to the supporting-casing, means carried by the drill-casing whereby the casing can be turned on its longitudinal axis to feed the same, said drill-casing and said drill-casing-engaging member being so arranged as to permit the drill-casing to be automatically fed forward on its longitudinal axis at each forward impulse of the hammer, and means for moving said member carried by the supporting-casing to move the drill-casing along its longitudinal axis through the supporting-casing substantially as shown and described.

5. An apparatus of the class described, comprising a drilling mechanism consisting of a drill-casing and a hammer mechanism reciprocally mounted therein, means for operating said hammer mechanism, a supporting-casing consisting of a longitudinal tubular member for receiving said drill-casing, said drill-casing capable of having longitudinal movement through said supporting-casing, a screw connection between said supporting-casing and said drill-casing, means for turning said drill-casing on its longitudinal axis to feed the same, and means for moving said drill-casing longitudinally through said supporting-casing, all being arranged substantially as shown and described.

6. An apparatus of the class described, comprising a drilling mechanism consisting of a drill-casing and a hammer mechanism reciprocally mounted therein, means for operating said hammer mechanism, a supporting-casing consisting of a longitudinal tubular member for receiving said drill-casing, said drill-casing capable of having longitudinal movement through said supporting-casing, a screw connection between said supporting-casing and said drill-casing, means for turning said drill-casing on its longitudinal axis to feed the same, means for moving said drill-casing longitudinally through said supporting-casing, said drill-casing and said supporting-casing and their screw connections being arranged to permit automatic feed of the drill-casing forward through the supporting-casing at each forward impulse of the hammer without rotating the casing, substantially as shown and described.

7. An apparatus of the class described, comprising a drilling mechanism consisting of a longitudinal tubular casing, having an external thread, a hammer-barrel fitted within said casing, a drill-chuck within said hammer-barrel at its forward end, a closure-plug within said hammer-barrel at its rearward end, inlet-apertures communicating with the interior of the hammer-barrel, and the interior of the drill-casing, exhaust-ports for the hammer-barrel, a reciprocating hammer within the hammer-barrel, means for admitting compressed air into the drill-casing, a handle member secured to the drilling-casing whereby the same can be turned on its longitudinal axis a tubular supporting-casing having a bore for receiving the drill-casing, a worm-gear mounted in said supporting-casing, and adapted to mesh with the thread on the drill-casing, a hand-wheel for turning said worm-gear, said worm-gear and said drill-casing being arranged to allow the drill-casing to automatically feed forward at the forward movement of the hammer, while simultaneously permitting the drill-casing to be turned on its longitudinal axis by means of the handle, all being arranged substantially as shown and described.

8. An apparatus of the class described, comprising drilling mechanism consisting of an elongated tubular casing having an external thread, a tubular hammer-barrel fitted within said casing, a drill-chuck within said hammer-barrel at its forward end, a closure-plug within said hammer-barrel at its rearward end, inlet-apertures connecting with the interior of the hammer-barrel and the interior of the drill-casing, exhaust-ports for the hammer-barrel, a reciprocating hammer within the hammer-barrel, means for admitting compressed air into the drill-casing, a handle member secured to the drill-casing whereby the same can be turned on its longitudinal axis, a tubular supporting-casing having a bore for receiving the drill-casing, a worm-gear mounted in said supporting-casing and adapted to mesh with the threads on the drill-casing, a hand-wheel for turning the worm-gear, said worm-gear and said drill-casing being arranged to allow the drill-casing to be automatically fed forward by the forward movements of the hammer, while simultaneously permitting the drill-casing to be turned on its longitudinal axis by means of the handle, and means for mounting said supporting-casing to permit adjustment of the drilling mechanism with the longitudinal axis of the drill-casing at any angle substantially as shown and described.

9. In a rock-drill, a supporting-casing, a drill-casing, screw connections between the supporting and drill casings, and means whereby the drill-casing can be ejected from the supporting-casing without turning the same on its longitudinal axis.

10. In an apparatus of the class described, the combination with the drill-casing, a supporting-casing for receiving the drill-casing, of means for screwing the drill-casing through the supporting-casing, and means carried by the supporting-casing and coöperating with the drill-casing for permitting the drill-casing to be automatically fed through the supporting-casing in one direction by the impulse of the drill-hammer, substantially as shown and described.

11. In an apparatus of the class described, the combination with the drill-casing, a supporting-casing for receiving the drill-casing, of means for screwing the drill-casing through the supporting-casing, and means carried by the supporting-casing and coöperating with the drill-casing for permitting the drill-casing to be automatically fed through the supporting-casing in one direction by the impulse of the drill-hammer and means coöperating with said last-named means for moving the drill-casing through the supporting-casing in the direction of its longitudinal axis without turning the drill-casing substantially as shown and described.

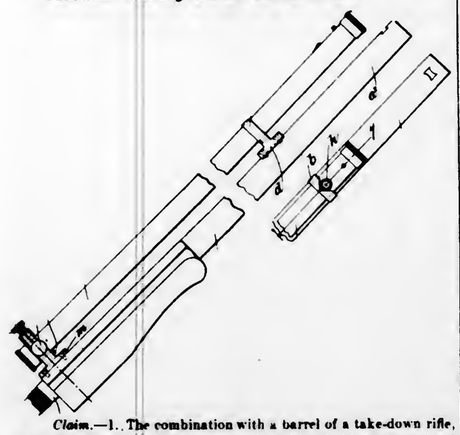
12. An apparatus of the class described, the combination with the drilling mechanism including a drill-casing and a reciprocating hammer, of a supporting-casing adapted to receive said drill-casing, screw connections between said drill-casing and said supporting-casing, means carried by the drill-casing whereby the same can be turned on its longitudinal axis to feed it through the supporting-casing, means carried by the supporting-casing for permitting the drill-casing to be moved in the direction of its longitudinal axis through the supporting-casing without rotating the drill-casing, substantially as shown and described.

13. An apparatus of the class described, the combination with the drilling mechanism including a drill-casing and a reciprocating hammer, of a supporting-casing adapted to receive said drill-casing, screw connections between said drill-casing, and said supporting-casing, means carried by the drill-casing whereby the same can be turned on its longitudinal axis to feed it through the supporting-casing, means carried by the supporting-casing for permitting the drill-casing to be moved in the direction of its longitudinal axis through the supporting-axis without rotating the drill-casing, and for permitting the drill-casing to be fed through the supporting-casing, by each forward impulse of the drill-hammer, independent of the rotation of the drill upon its longitudinal axis substantially as shown and described.

14. An apparatus of the class described, comprising in combination with a drilling mechanism including a drill-casing and a reciprocating hammer therein, of a supporting-casing, means for feeding the drill-casing through the supporting-casing, by rotating the same on its longitudinal axis and means for feeding the drill-casing through the supporting-casing without rotating the drill-casing on its longitudinal axis, substantially as shown and described.

15. In a rock-drill, a supporting-casing, a drill-casing, connections between the supporting and drill casings whereby the drill-casing can be fed through the supporting-casing, and means whereby the drill-casing can be ejected from the supporting-casing without turning the same on its longitudinal axis.

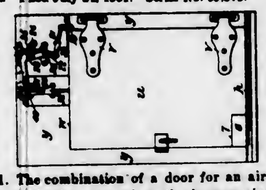
812,376. RIFLE-TELESCOPE. FREDERICK L. SMITH, Chicopee Falls, Mass. Filed Aug. 26, 1903. Serial No. 171,155.



Claim.—1. The combination with a barrel of a take-down rifle, of a telescope mounted thereon provided with suitable horizontal and vertically-disposed cross-hairs, suitable mounts for the telescope located near each end of the barrel and in which the telescope is longitudinally slidable, a stop on the telescope to engage one of said mountings to prevent the rotation of the telescope when in an adjusted postion, and to locate said cross-hairs in their proper position.

2. The combination with a barrel of a take-down rifle, of a telescope mounted thereon provided with suitable horizontal and vertically-disposed cross-hairs, suitable mounts for the telescope located near each end of the barrel and in which the telescope is longitudinally slidable, a stop on the barrel to engage one of said mountings to prevent the rotation of the telescope when in an adjusted position and to locate said cross-hairs in their proper position, together with devices to effect the vertical and horizontal adjustment of the telescope.

812,377. DOOR-FRAME, DOOR, AND ADJUNCTIVE MECHANISM FOR AIR-TIGHT COMPARTMENTS. S. PRICE STEVENSON, Chester, Pa. Filed July 24, 1901. Serial No. 69,575.



Claim.—1. The combination of a door for an air-tight apartment; a door-frame having a port above the door-opening proper and adapted to permit the passage of a rail with a free space between its track and the upper portion of said port; a shutter hinged to the door-frame above said port, said shutter having a vertical slot extending from its lower edge throughout a portion of its height, whereby said shutter may be swung downward to close the interspace between said port and the top and sides of said rail, substantially as set forth.

2. The combination of a door for an air-tight apartment; a door-frame comprising jambs *a*, and *b*, a lintel *c*, blocks *k*, *l*, *r*, and *q*, a casing *y*, provided with a port which is adapted to permit the passage of a rail above said door with a free space between said track and the upper portion of said port; a shutter hinged to the door-frame above said port and provided with a slot extending vertically from its lower edge throughout a portion of its height, whereby said shutter may be swung downward to close the interspace between said port and the top and sides of said rail, substantially as set forth.

3. The combination of a door for an air-tight apartment; a door-frame therefor provided with a port arranged above the door-opening, and adapted to permit the passage of a rail with a free space between its track and the upper portion of said port; a shutter hinged to the door-frame above said port and having a vertical slot extending from its lower edge throughout a portion of its height, the lower margin of said shutter extending downward below the bottom of said port and into the opening for the door, but substantially flush with the face of the door-frame, whereby said shutter can be swung downwardly to close the interspace between said port and the sides and top of the rail, and the door proper can be closed upon the lower margin of said shutter, substantially as set forth.

4. A door for an air-tight apartment; a door-frame having a port adapted to permit the passage of a suspended rail with a free space between the track thereof and the top of said port; a shutter hinged to the door-frame above said port and adapted to close the opening about the top and sides of said rail; and actuating mechanism, substantially as set forth, operatively connecting said shutter with said door, whereby the shutter is positively opened and closed by the movement of the door in opening and closing.

5. In a door and door-frame for air-tight apartments a port for a suspended rail-track, and a shutter fitted to close said port, in combination with a positive means of opening and closing said shutter from the motion of the door, and arranged to close shutter before closing the door and to open the door before opening the shutter as and for the purpose set forth.

6. In a mechanism for operating a shutter and door for closing the doorway of air-tight apartments, a cam connected to and receiving motion from the opening and closing of the door, and having a slot therein engaging a roller connected with said shutter, said slot having such configuration as to impart motion to the shutter during a portion of the motion of the door and hold the shutter in fixed position during another portion of such motion as set forth.

7. In a door-frame and door for air-tight apartments, a port for a suspended rail-track and a shutter fitted to open and close said port, in combination with a mechanism connecting said shutter with said door arranged to open said shutter as soon as the door has opened sufficiently to clear said shutter and to hold said shutter open during the further opening of the door substantially as set forth.

8. In a refrigerating apparatus, the combination of a housing having a door adapted to close an entrance, and an opening above the door, plates adapted to cover said opening, a lever, connections between said plates and the said lever, a means for actuating the lever and thereby opening or closing said plates simultaneously with the opening or closing of the door.

812,378. PAPER-BAG MACHINE. FREDERICK E. STRASBURG, Rumford Falls, Me., assignor to Continental Paper Bag Company, a Corporation of Maine. Filed Sept. 29, 1904. Serial No. 226,551.

Claim.—1. The combination of a revoluble carrier, a folding-bed fixed thereon, means mounted coaxial with the folding-bed and revolving therewith to open out the forward end of a tucked-paper tube and fold the same down into a diamond form, an oscillatable lever pivotally mounted in the revoluble carrier, a front finger 115 mounted in the free end of the oscillatable lever for entering the mouth of the bag-blank to hold the lower ply thereof to the folding-bed during the formation of the diamond fold, all combined and operating together substantially as described.

2. The combination of a revoluble folding-bed having side clips 100, 101 thereon, a pair of oppositely-disposed trunnions 134, 135 mounted for oscillation about their own axes respectively, and for revolution with the folding-bed, a pair of gripper-fingers carried by each trunnion, said fingers being mounted in their respective trunnions for vibration inwardly and outwardly with respect to the folding-bed and one of each pair of said fingers being mounted for vibration toward and away from the other finger of its respective pair, all combined and operating together substantially as described.

3. The combination of a revoluble folding-bed 102, a transfer-roll 93 and a revoluble folding-bed 187 each having side clips there-

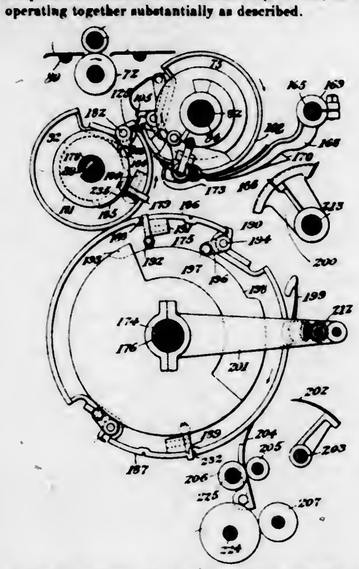
on: means coacting with the first folding-bed to open out and fold down into a diamond form the forward end of a tucked-paper tube, and means coacting with the second folding-bed to fold the rear and

gases and vapors from said distilling and combustion chambers, said intermediate chambers communicating with the flame-trunk, and means supplying heated air to said flame-trunk.

812,381. COMBINED HEATING AND COOKING STOVE. JAMES W. TATUM, Durham, N. C., assignor of one-half to DeWitt C.

adapted to be secured one in advance of the other to the forward end of a plow-beam, a lifter, pivoted to the front clamp, formed with a rearwardly-extending arm, passing through and normally supported

on: means coacting with the first folding-bed to open out and fold down into a diamond form the forward end of a tucked-paper tube, and means coacting with the second folding-bed to fold the rear and front flaps of the diamond fold to form a bag-bottom, all combined and operating together substantially as described.



4. The combination of a revoluble folding-bed 102, a transfer-roll 92 and a revoluble folding-bed 187 each having a pair of side clips and a front clip thereon; means coacting with the first folding-bed for forming a diamond fold on the forward end of a tucked-paper tube, and means coacting with the second folding-bed for folding the flaps of the diamond fold to form a bag-bottom, all combined and operating together substantially as described.

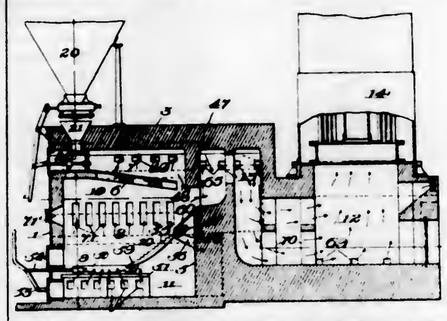
5. The combination of a revoluble folding-bed 102, a transfer-roll 92 and a revoluble folding-bed 187 each having means for holding a bag-blank thereon; means coacting with the first folding-bed to open out and fold down into a diamond form the forward end of a bag-blank and means coacting with the second folding-bed to fold the rear and front flaps of the diamond fold, all combined and operating together substantially as described.

812,379. DEVICE FOR RECOVERING ARTICLES FROM DEEP WELLS. EDWARD A. STUBLER, Oil City, Pa. Filed Oct. 10, 1905. Serial No. 282,133.

Claim.—As a new article of manufacture, a tool of the class described, the exterior of which fits the bore of the well and terminates at the bottom in an edge, and which is formed with a two-part bore, the upper part of said bore being cylindrical and the lower part thereof flaring outwardly from said cylindrical part to the lower edge of the tool; said flaring part being formed with thread-cutting members and said cylindrical part being formed with a continuous thread which extends upwardly from said thread-cutting members; whereby said tool is adapted to cut a screw-thread upon articles of different diameters and to engage the screw-thread on said cylindrical part therewith.

812,380. FURNACE. TOSABURO SUZUKI, Sumamura, Japan. Filed Mar. 3, 1905. Serial No. 248,310.

Claim.—1. A furnace comprising a main combustion-chamber, a secondary combustion-chamber, a flame-trunk connecting said chambers, a distilling-chamber formed in said main combustion-chamber, intermediate mixing-chambers adapted to receive distilled gases and vapors from said distilling and combustion chambers, said intermediate chambers communicating with the flame-trunk, and means supplying heated air to said flame-trunk.



2. A furnace comprising a combustion-chamber having a main outlet-passage for the products of combustion, means supplying heated air to said outlet, a distilling-chamber formed in said combustion-chamber, and means whereby the distilled gases are conveyed to the outlet-passage.

3. A furnace comprising a combustion-chamber having a main outlet-passage, air chambers or jackets surrounding said combustion-chamber, means controlling the admission of air to said chambers, said air-chambers having openings terminating in said main outlet-passage, mixing-chambers located between said combustion and air chambers, a distilling-chamber formed in said combustion-chamber, means whereby the distilled gases and vapors are conveyed to said mixing-chambers, and means whereby said gases and vapors are conveyed to said main outlet-passage.

4. A furnace comprising a main combustion-chamber, a secondary combustion-chamber, a flame-trunk connecting said chambers, a distilling-chamber formed in said main combustion-chamber, intermediate mixing-chambers adapted to receive distilled gases and vapors from said distilling and combustion chambers, said intermediate chambers communicating with the flame-trunk, means supplying heated air to said flame-trunk, and means whereby heated air may be introduced in said secondary chamber.

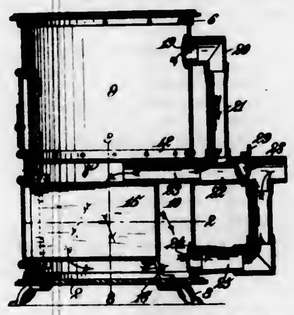
5. A furnace comprising a combustion-chamber, having a main outlet-passage for the products of combustion, means supplying heated air to said outlet, a distilling-chamber formed in said combustion-chamber, means whereby the distilled gases are conveyed to the outlet-passage, and a secondary combustion-chamber connected with said main outlet-passage.

6. A furnace comprising a combustion-chamber, having a main outlet-passage for the products of combustion, means supplying heated air to said outlet, a distilling-chamber formed in said combustion-chamber, means whereby the distilled gases are conveyed to the outlet-passage, a secondary combustion-chamber connected with said main outlet-passage, and means whereby heated air may be supplied to said last-mentioned chamber.

7. A furnace comprising a combustion-chamber having a main outlet-passage, air chambers or jackets surrounding said combustion-chamber, means controlling the admission of air to said air-chambers, said air-chambers having openings terminating in said main outlet-passage, mixing-chambers located between said combustion and air chambers, a distilling-chamber formed in said combustion-chamber, means whereby the distilled gases and vapors are conveyed to said mixing-chambers, means whereby said gases and vapors are conveyed to said main outlet-passage, and a secondary chamber connected with said main outlet and adapted to receive the products of combustion, gases and air.

8. A furnace comprising a combustion-chamber having a main outlet-passage, air chambers or jackets surrounding said combustion-chamber, means controlling the admission of air to said chambers, said air-chambers having openings terminating in said main outlet-passage, mixing-chambers located between said combustion and air chambers, a distilling-chamber formed in said combustion-chamber, means whereby the distilled gases and vapors are conveyed to said mixing-chambers, means whereby said gases and vapors are conveyed to said main outlet-passage, a secondary combustion-chamber connected with said main outlet and adapted to receive the products of combustion, gases and air, and means supplying heated air to said secondary chamber.

812,381. COMBINED HEATING AND COOKING STOVE. JAMES W. TATUM, Durham, N. C., assignor of one-half to Dewitt C. Mangum, Durham, N. C. Filed Apr. 14, 1905. Serial No. 255,645.



Claim.—1. In a combined heating and cooking stove, a shell having a horizontal partition extending entirely across the same and dividing the shell into two compartments, one located directly above the other, an oven located in the lower compartment, flues located entirely outside the shell and communicating with said compartments, and a damper located in one of said flues and arranged to cause the products of combustion from the upper compartment to pass directly into the lower compartment or to the chimney.

2. In a combined heating and cooking stove, a shell having a horizontal partition therein extending entirely across the same and dividing the shell into two compartments one located directly above the other, an oven located in the lower compartment, said oven being smaller than said compartment whereby a space is provided entirely around the closed walls thereof, flues located entirely outside the shell and having communication with the said compartments, and a damper in one of said flues arranged to cause the products of combustion to pass from the upper compartment directly into the lower compartment or to the chimney.

3. In a combined heating and cooking stove, a shell a horizontal partition extending entirely across the same and dividing the shell into two compartments, one located directly above the other, two pipes having communication with the lower compartment, a pipe having communication with one of the said two pipes and with the upper compartment, and a damper arranged to cause the products of combustion to pass from the upper compartment directly into the lower compartment or to the chimney.

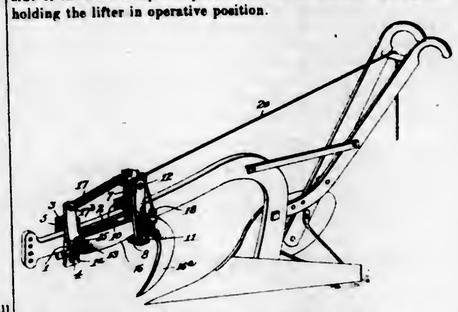
4. In a combined heating and cooking stove, a shell, a horizontal partition extending entirely across the same and dividing the shell into two compartments, one located directly above the other, an oven located in the lower compartment and elevated above the bottom thereof, two pipes having communication with the lower compartment, a pipe communicating at one end with one of the said two pipes and at its other end with the upper compartment, and a damper arranged to cause the products of combustion to pass from the upper compartment directly into the lower compartment or to the chimney.

5. In a combined heating and cooking stove, a shell, a horizontal partition extending entirely across the shell and dividing the same into two compartments, one located directly above the other, an oven in the lower compartment, a pipe extending into said compartment and having its inner end disposed above the oven, a second pipe leading from the bottom of the lower compartment and communicating with the first-named pipe, a flue leading from the upper compartment and communicating with the said pipe that extends into the lower compartment, and a damper arranged to cause the products of combustion to pass from the upper compartment directly into the lower compartment or to the chimney.

812,382. ATTACHMENT FOR PLOWS. ANTHONY THIELEN, Bryant, Iowa. Filed Oct. 26, 1905. Serial No. 284,512.

Claim.—1. An attachment for plows comprising front and rear clamps, adapted to be secured one in advance of the other to the forward end of a plow-beam, and a lifter, pivoted to the front clamp, formed with a rearwardly-extending arm, passing through and normally supported by the rear clamp, and a hook extending downwardly from the rear side of the rear clamp to a point under the latter.

2. An attachment for plows comprising front and rear clamps, adapted to be secured one in advance of the other to the forward end of a plow-beam, a lifter, pivoted to the front clamp, formed with a rearwardly-extending arm, passing through and normally supported by the rear clamp, and a hook extending downwardly from the rear side of the rear clamp to a point under the latter and a spring for holding the lifter in operative position.



3. An attachment for plows comprising front and rear clamps, a lifter, pivoted to the front clamp, formed with an upwardly-projecting arm, a rearwardly-extending arm, normally supported by the rear clamp, and a hook extending downwardly from the rear side of the rear clamp to a point under the latter, and a spring for holding the lifter in operative position, connected at one end to the rear clamp and at the other end to the upwardly-projecting arm.

4. An attachment for plows comprising front and rear clamps, a spacing-plate within the clamps, a lifter, pivoted to the front clamp, formed with an upwardly-projecting arm, a rearwardly-extending arm, normally supported by the rear clamp and a hook extending downwardly from the rear side of the rear clamp to a point under the latter, and a spring, for holding the lifter in operative position, connected at one end to the rear clamp and at the other end to the upwardly-projecting arm.

5. An attachment for plows comprising a front clamp, a rear clamp having a hole at its upper end, a lifter, pivoted to the front clamp, formed with an upwardly-projecting arm, having a hole at its upper end, a rearwardly-extending arm, normally supported by the rear clamp, and a hook extending downwardly from the rear side of the rear clamp to a point under the latter, and a tension-spring for holding the lifter in operative position, having hooked ends engaging the holes of the rear clamp and the upwardly-projecting arm respectively.

6. An attachment for plows comprising a front clamp consisting of a pair of plates and lower and upper bolts whereby the front clamp is secured to the forward end of a plow-beam, a pivot-stud secured to the front clamp, a rear clamp, adapted to be secured to the plow-beam behind the front clamp, a lifter, mounted upon the pivot-stud, formed with a rearwardly-extending arm, passing through and normally supported by the rear clamp, and a hook extending downwardly from the rear side of the rear clamp to a point under the latter.

7. An attachment for plows comprising front and rear clamps, adapted to be secured one in advance of the other to the forward end of a plow-beam, a spacing-plate within the clamps, a pivot-stud extending through the spacing-plate and the front clamp, a lifter, mounted upon the pivot-stud, formed with a rearwardly-extending arm, passing through and normally supported by the rear clamp, and a hook extending downwardly from the rear side of the rear clamp to a point under the latter.

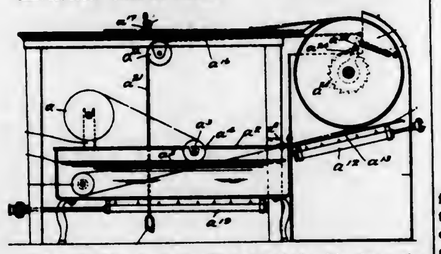
8. An attachment for plows comprising a front clamp, adapted to be secured to the forward end of a plow-beam, a rear clamp consisting of a pair of plates and a lower bolt, and an upper bolt whereby the rear clamp is secured behind the front clamp, to a plow-beam and a lifter pivoted to the outer clamp, formed with a rearwardly-extending arm, passing through and normally supported by the lower bolt of the rear clamp, and a hook extending downwardly from the rear side of the rear clamp to a point under the latter.

9. An attachment for plows comprising a front clamp, adapted to be secured to the forward end of a plow-beam, a rear clamp, adapted to be secured to the plow-beam behind the front clamp, and consisting of outer, intermediate and inner plates, lower and upper spacing-collars between the intermediate and inner plates, a lower bolt securing the outer, intermediate and inner plates and the lower spacing-collar together, an intermediate bolt securing the outer and intermediate plates together, an upper bolt securing the intermediate and inner plates and the upper spacing-collar together, a lifter,

pivoted to the front clamp, formed with a rearwardly-extending arm, passing through and normally supported by the lower spacing-collar and limited in its upward movement by the upper spacing-collar, and a hook extending downwardly from the rear side of the rear clamp to a point under the latter.

10. An attachment for plows comprising a front clamp, a rear clamp having an eye at its upper end, a lifter, pivoted to the front clamp, formed with a rearwardly-extending arm normally supported by the rear clamp, and a hook extending downwardly from the rear side of the rear clamp to a point under the latter, and having an eye at its heel, and a lifting flexible connection connected to the hook-eye and passing through the clamp-eye.

812,383. METHOD OF MAKING INNERSOLES AND THE LIKE. ANDREW THOMA, Cambridge, Mass., assignor to Clifton Manufacturing Company, Boston, Mass., a Corporation of New Jersey. Filed Mar. 13, 1905. Serial No. 249,683.



Claim.—1. The herein-described method of making innersoles, consisting of providing an innersole foundation of leather or other suitable material, and a fabric strip of cementitious coated reinforce material, softening and rendering pliable said strip in a liquid bath, rendering the coating sticky by heat and applying the same to said innersole foundation while still moist.

2. The herein-described method of making innersoles, consisting of providing an innersole foundation of leather or other innersole-foundation material, and a fabric strip of reinforce material, applying to one side of said strip a coating of cement capable of adhering to said foundation material, permitting said coating to dry, rendering pliable said strip by soaking it in a liquid bath until the liquid has permeated and softened the entire body of the fabric, and cementing the same to said innersole foundation while still in said pliable, softened condition.

3. The herein-described method of making innersoles, consisting of providing an innersole foundation of leather or other suitable material, and a fabric strip of reinforce material, applying to said strip a coating of cementing material which is unaffected by water, softening and rendering pliable said strip in a liquid bath, subjecting said coating to an intense dry heat, and cementing the same to said innersole foundation while still moist.

4. The herein-described method, consisting of applying to a strip of fabric a base of sticky compound, adhesive to the fabric, then applying to said base a normally non-sticky compound which is capable of becoming sticky under heat, permitting the same to dry and set, and then subjecting the coated side only of said fabric strip to an intense dry heat, and applying it under pressure to the article to be reinforced.

5. The herein-described method, consisting of applying to a strip of fabric a base of sticky compound, adhesive to the fabric, then applying to said base a normally non-sticky compound which is capable of becoming sticky under heat, permitting the same to dry and set, then passing said coated strip through a hot liquid bath, then subjecting the same to an intense dry heat, and applying the same while still moist to the article to be reinforced.

6. The herein-described method of forming a reinforcing-strip, consisting of applying to one side of a strip of fabric a base of sticky compound adhesive to the fabric, then applying to said base a normally non-sticky non-oxidizing compound unaffected by water, and capable of becoming sticky under dry heat, and then drying the same.

7. The herein-described method, consisting in providing a strip of reinforcing material with a cementitious coating whose cementitious character is not injured by water, then immersing said strip in hot water a sufficient time to soften and render the same pliable, then subjecting the coated side of the strip momentarily to a dry heat, and applying the same under pressure to the article to be reinforced.

8. The herein-described method, consisting of coating a strip of fabric with a base of sticky compound adhesive to the fabric, coating said base with a normally non-sticky compound, permitting the same to dry and set, rendering said coating sticky by the application of heat, and forcibly pressing together, when cold, said coated fabric and the article to be reinforced.

9. The herein-described method, consisting of providing a strip of fabric with a coating having a base adhesive to the fabric and a normally non-sticky outer surface capable of being rendered sticky by heat and of remaining sticky for a considerable time thereafter when cold, permitting said coating to dry and set, applying an intense heat to said coated fabric for developing the said stickiness of said coating, permitting the same to cool, and then forcibly pressing the cold, sticky fabric in place on the article being reinforced.

812,384. REINFORCING FABRIC FOR INNERSOLES. ANDREW THOMA, Cambridge, Mass., assignor to Commonwealth Trust Company, trustee, Buffalo, N. Y. Filed May 15, 1905. Serial No. 260,558.

Claim.—1. As an article of manufacture, a strip of reinforcing fabric, coated on one side with a base of sticky compound adhesive to the fabric, and an external coating on said base of non-sticky, non-oxidizing compound unaffected by water, and capable of becoming sticky under dry heat.

2. As an article of manufacture, a strip of reinforcing fabric, having a coating on one side, normally tacky next to the fabric and decreasingly tacky toward the exterior surface of the coating, which can be rolled without sticking the roll together, said coating being rendered exceedingly sticky by the application of dry heat.

3. As an article of manufacture, a strip of reinforcing fabric, coated on one side with a base of normally sticky compound and with an external coating thereon of normally non-sticky compound unaffected by water and capable of being rendered sticky by heat.

4. As an article of manufacture, a strip of reinforcing fabric, having a coating on one side whose external surface is normally non-sticky, said coating being capable of being rendered sticky by heat and being thereafter capable of adhesion when cold.

5. As an article of manufacture, a strip of reinforcing fabric, having an external coating normally non-sticky, but capable of being rendered sticky by heat, and containing a large percentage of gutta-percha, combined with ingredients maintaining said stickiness when cold.

6. As an article of manufacture, a strip of reinforcing fabric, having a base containing a large percentage of resinous residuum of petroleum, and an external coating containing a large percentage of resinous gutta-percha.

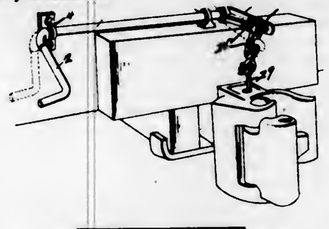
7. As an article of manufacture, a strip of reinforcing fabric, having a base containing a resinous residuum of petroleum and a sticky vegetable gum, and an external coating thereon containing a small percentage of said residuum of petroleum, and a large percentage of said vegetable gum and resinous gutta-percha, the latter predominating.

812,385. OPERATING MECHANISM FOR AUTOMATIC CAR-COUPLINGS. EDGAR E. TURNEY, Peru, Ind., assignor of one-third to Nelson H. Tunks and one-third to Katie C. Heinig, Peru, Ind. Filed Nov. 1, 1905. Serial No. 285,374.

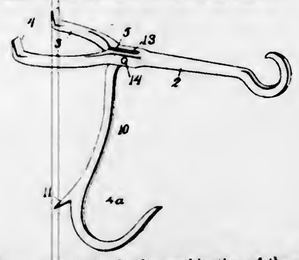
Claim.—1. In a means for operating automatic car-couplers, the combination with the coupler-lock, of an operating-rod, a bushing secured against rotation upon said rod, an arm adjustable upon said bushing, and a clevis slidably connected with the outer end of said arm and connected at its lower end with the coupler-lock, substantially as described.

2. In a means for operating automatic car-couplers, the combination with the coupler-lock, of an operating-rod, a bushing secured against rotation upon said rod, an arm adjustable upon said bushing, and a clevis connecting the arm with the coupler-lock, said clevis being slidably carried at the outer end of said arm and having means for adjusting the same in the direction of its length, substantially as described.

3. In a means for operating automatic car-couplers, an operating-rod having a squared end, a bushing having a square perforation to fit upon said end and held against rotation thereon, said bushing having a flange provided with radial teeth, an arm mounted upon the bushing and also provided with radial teeth to engage the teeth upon the flange, said arm having an elongated slot at its outer end, a nut upon the rod to secure the arm when adjusted relative to the bushing, and a clevis connecting the slotted end of the coupler-arm with the coupler-lock, said clevis consisting of two parts having interengaging teeth to permit the same to be adjusted in the direction of their length, and means for securing said clevis parts in adjusted position, substantially as described.

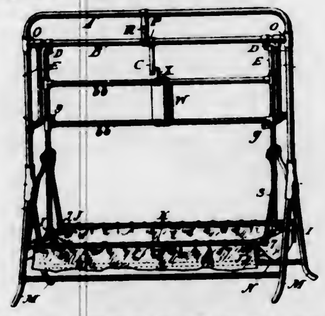


812,386. SUSPENSION-BRACKET. FREDERICK H. WALDEN, Worcester, Mass. Filed Apr. 30, 1904. Serial No. 205,732.



Claim.—In a painter's hook, the combination of the member having the hook at one end and a pair of upwardly-reaching engaging spurs at its other end, and the brace pivoted between said spurs at one end and having the downwardly-projecting spur near its other end and the large hook; said parts being arranged to permit said shank to be swung up parallel with said member with its large hook encircling the smaller hook of said member.

812,387. SWINGING HAMMOCK. MERRIAN N. WERTS, Thomasville, Ga. Filed Jan. 21, 1905. Serial No. 242,161.



Claim.—1. In a device of the class described consisting of a main frame, folding legs at bottom thereof, a turnable horizontal cross-bar at the top of main frame, a hammock folding frame pivoted to said bar, adjusting-levers secured to the ends of said bar, and guides at the bottom of said levers, limiting the movement of hammock-frame substantially as shown and described.

2. In a device of the class described, comprising a main frame consisting of two end pieces with folding legs at bottom, a horizontal top bar, and two horizontal bars secured to the folding legs; a turnable horizontal bar near the top of the main frame, adjusting-levers secured to each end of said bar, a hammock-frame and guides secured to the bottom of said levers for limiting the movement of the hammock-frame, a striking-lever in line of adjusting-levers, in center of said turnable bar, and a clockwork-motor mounted on hammock-frame, substantially as described.

3. A main frame comprising two upright end members, folding legs at bottom thereof, a horizontal turnable bar mounted near the top of upright end members, adjusting-levers secured to the turnable bar at each end thereof, a striking-lever secured to said bar, a hammock-frame swinging from knife-edge hanger-brackets on said bar, and a clockwork-motor engaging the striking-lever, substantially as described.

4. In a device of the class described, a main frame with a turnable horizontal bar near the top, with a striking-lever in center secured thereto and a clamp clasping it near said striking-lever and also attached to the top bar of main frame, and loosened or tightened to both top bar and said turnable horizontal bar by means of a lock-bolt so that when it is tightened it will hold the turnable horizontal bar rigid thereby securing the striking-lever in a rigid position to receive the pallet-wire and so remain until changed by the adjusting-lever, enabling the clockwork-motor to swing the hammock on level and unlevel places alike, substantially as described.

5. In a device of the character described a main frame composed of top bar, end bars with folding legs at bottom, bottom bars horizontally attached to said legs, a cylindrical turnable bar with adjusting-levers, a striking-lever, and a clamp attached thereto, a T-bracket with a socket for the reception of the cylindrical turnable cross-bar, said T-bracket with socket being a permanent fixture of the main frame and a support for the turnable bar that supports the hammock, the said cylindrical bar with knife-edge brackets on same, and a hammock suspended thereto by two perpendicular bars hanging on the two knife-edge brackets by a sharp oblong eye in top of said perpendicular bars which supports the hammock at bottom of same, substantially as described.

6. In a device of the class described, a main frame with folding legs at bottom, with a turnable supporting-bar with ends protruding into the socket of T-bracket, with knife-edge brackets, a striking-lever and adjusting-levers attached thereto, two perpendicular rods supported on said knife-edged brackets and two horizontal bars attached to said perpendicular rods, with a clockwork-motor attached thereto, a hammock hinged to bottom of said perpendicular bars, in a way that said hammock will fold upwardly and fall to a level supported by four stay-rods with lower ends passing through turnable sockets at each corner, said sockets being turnable in such way that they will allow the stay-rods to slip through them and slip upwardly along said rods, thus allowing the hammock to be folded together closely to the main frame so that when the legs of main frame are folded together the whole structure will occupy but little room as hereinbefore substantially described.

812,388. ACETYLENE-GAS APPARATUS. PAUL H. WIDMAN, Denver, Colo. Filed May 13, 1905. Serial No. 260,337.

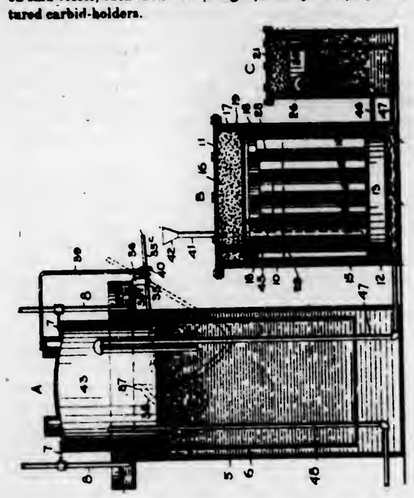
Claim.—1. In an acetylene-gas apparatus, in combination with a gasometer, a generating-chamber surmounted by a purifying-chamber and constructed to contain a gas-generating agent, a water-tight cooling-chamber within said generating-chamber, means to admit the gas generated from said agent into said purifying-chamber, and means to conduct the gas from the purifying-chamber through said cooling-chamber to the gasometer.

2. In an acetylene-gas apparatus, in combination with a gasometer, a generating-chamber, a horizontally-disposed foraminated partition dividing said generating-chamber into a generating-compartment constructed to contain a gas-generating substance and a purifying-chamber constructed to contain a purifying agent, and a water-tight cooling-chamber inside said generating-chamber spaced from its walls and communicating with the gasometer and with the purifying-chamber.

3. In an acetylene-gas apparatus, in combination an expandible gasometer, a generator, two separated chambers each containing a purifying agent, a cooling-chamber, a tank, means to convey gas from said generator successively through one of said purifier-chambers and said cooling-chamber into said tank, and means to conduct the gas arising above the surface of the water in the latter, through the second purifying-chamber into the gasometer and below the surface of the water contained therein.

4. In an acetylene-gas apparatus, a generator comprising a closed receptacle, a horizontally-disposed perforated partition divid-

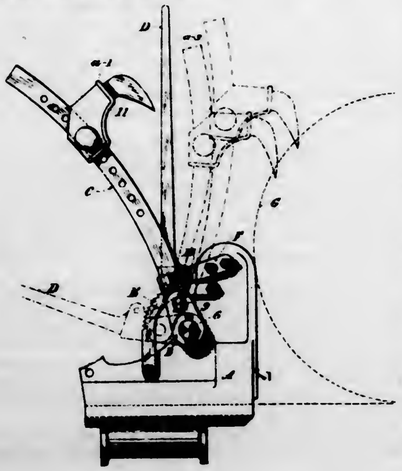
ing the interior of said receptacle into a generating and a superposed purifying compartment, a water-tight vessel located inside and spaced from the former, a series of intercommunicating shells located on said vessel, each shell containing a plurality of superposed, apertured carbid-holders.



5. In an acetylene-gas apparatus, in combination a gasometer, a water-reservoir comprising a generating-chamber and a superposed purifying-chamber, a cooling-chamber within said generating-chamber, a tank, a second purifying-chamber surmounting same, means to convey gas from the generating-chamber successively through the first-named purifying-chamber and the cooling-chamber into the tank, and means to conduct the gas arising above the surface of the water in the latter through the second purifying-chamber into the gasometer and below the surface of the water contained therein.

6. In an acetylene-gas apparatus, in combination a gasometer, a water-reservoir comprising a generating-chamber and a superposed purifying-chamber, a cooling-chamber within said generating-chamber, a tank, means to convey gas from the generating-chamber successively through the purifying-chamber and the cooling-chamber into the tank, and means to conduct the gas arising above the surface of the water in the latter, into the gasometer and below the surface of the water contained therein.

812,389. LOG-DOG. CHARLES W. WILLETT, Portland, Oreg. Filed Aug. 14, 1905. Serial No. 274,156.



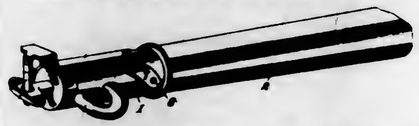
Claim.—1. In a sawmill-dog mechanism on a sliding knee of a movable carriage, a combination comprising a dog-bar pivotally mounted at its foot at a suitable height in the lower socket or pair of jaws of a knuckle B and carrying a dog provided with means to secure and adjust the same thereon; an operating-lever D pivotally mounted at its toe in the upper socket or pair of jaws of the knuckle B, adapted to engage the socket with its heel and be guided over a toothed quadrant-bar in sliding engagement, also provided with means at its lower end to automatically lock the lever on or release it from the teeth of the quadrant; a knuckle B, at its lower end, pivotally mounted on the knee A and provided with upper and lower sockets or pairs of jaws, with an opening in the upper socket adapting it to be received and guided on the quadrant-bar and having perforations in each socket and the lower end for pivots; a toothed quadrant-bar adapted to receive the knuckle through an opening in its upper socket; a dog-bar fulcrum and stop-hook F fixedly secured to the knee A, all substantially a described.

2. In a sawmill-dog mechanism on a sliding knee of a movable carriage, a combination comprising a dog-bar pivotally mounted at its foot at a suitable height in the lower socket or pair of jaws of a knuckle B and carrying a dog provided with means to secure and adjust the same thereon; an operating-lever D pivotally mounted at its toe in the upper socket or pair of jaws of the knuckle B, adapted to engage the socket with its heel and be guided over a toothed quadrant-bar in sliding engagement, also provided with means at its lower end to automatically lock the lever on or release it from the teeth of the quadrant; a knuckle B, at its lower end, pivotally mounted on the knee A and provided with upper and lower sockets or pairs of jaws, with an opening in the upper socket adapting it to be received and guided on the quadrant-bar and having perforations in each socket and the lower end for pivots; a toothed quadrant-bar adapted to receive the knuckle through an opening in its upper socket; all substantially as described.

3. A sawmill-dog mechanism having a dog-bar pivotally mounted at its foot at a suitable height in the lower socket of a knuckle B and carrying a dog provided with means to secure and adjust the same thereon, an operating-lever D pivotally mounted at its toe in the upper socket of the knuckle B adapted to engage the socket with its heel and having means in the lower end to automatically lock it on or release it from the toothed quadrant E, also the knuckle-mounting B provided with an upper lever-socket and lower dog-bar socket, each perforated as also the lower end for pivots thereof, the upper socket having an opening to receive the quadrant-bar and guide the knuckle thereon, also the toothed quadrant-bar E adapted to receive the knuckle as stated and a dog-bar fulcrum and stop-hook F fixedly secured to a knee A, all substantially as described.

4. In a sawmill-dogging mechanism, a knuckle-mounting for the lever and dog-bar, having a pivot-mounting at its lower end, a lower socket or pair of jaws for the dog-bar, an upper socket or pair of jaws for the operating-lever, each perforated for the pivots thereof and the upper socket provided with an opening for the knuckle to receive and be guided on a quadrant-bar, substantially as described.

812,390. WHIFFLETREE-HOOK. GEORGE W. WILSON, Rockcreek, Idaho, assignor of one-half to James E. McEvoy, Hagerman, Idaho. Filed May 23, 1905. Serial No. 261,769.



Claim.—1. In a device of the class described, the combination of a whiffletree, a trace-receiving hook arranged at the side thereof, a trace-receiving tongue located at the end of the whiffletree, and a movable trace-holder provided with means for engaging the tongue and for simultaneously closing the entrance to the hook.

2. In a device of the class described, the combination of a whiffletree, a trace-receiving hook arranged at the side thereof, a trace-receiving tongue located at the end of the whiffletree, and a pivoted trace-holder arranged to swing upward and downward to open and close it and provided with means for confining a trace in engagement with the tongue or the hook.

3. In a device of the class described, the combination of a whiffletree, a trace-receiving hook arranged at the side thereof, a trace-receiving tongue located at the end of the whiffletree, and a pivoted trace-holder arranged to swing upward and downward to open and close it and provided with means for confining a trace in engagement with the tongue or the hook, said trace-holder being also provided with clamping means for holding it in its closed position.

4. In a device of the class described, the combination of a whiffletree provided at the side with a hook and having a tongue at the end, and a pivoted trace-holder arranged to open and close and provided with means for confining the trace in engagement with the hook or tongue, said trace-holder being also provided with a pair of clamping-jaws located at opposite sides of the whiffletree for retaining the trace-holder in its closed position.

5. In a device of the class described, the combination of a whiffletree provided at the side with a hook and having a tongue at the end, and a pivoted trace-holder provided with means for engaging the tongue for retaining the trace thereon, said trace-holder being also provided with a pair of clamping-jaws located at opposite sides of the whiffletree, the jaw adjacent to the hook being extended at the bill of the same to close the entrance to the hook.

6. In a device of the class described, the combination of a whiffletree provided with a side hook and having an end tongue, and a pivoted trace-holder provided with opposite clamping-jaws and having an extended end portion arranged to engage the tongue.

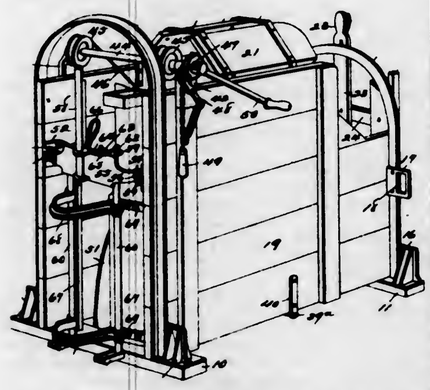
7. In a device of the class described, the combination of a whiffletree provided with an end tongue, and a pivoted trace-holder provided at opposite sides of the whiffletree with clamping-jaws and having a hook at its end for engaging the tongue.

8. In a device of the class described, the combination of a whiffletree provided with a tongue, and a pivoted trace-holder having laterally-extending clamping-jaws and provided with a hook consisting of an inner arm or shank and a narrow depending bill arranged to extend through the tongue.

9. In a device of the class described, the combination of a whiffletree provided with a hook having its bill arranged in spaced relation with the whiffletree, a pivoted trace-holder provided at opposite sides of the whiffletree with clamping-jaws for retaining the trace-holder in its closed position, the clamping-jaw adjacent to the hook being provided with an extension located in the space between the bill of the hook and the whiffletree.

10. In a device of the class described, the combination of a whiffletree having a side hook and provided at the end with a tongue, and a trace-holder comprising a body portion provided at its inner end with ears pivoted to the whiffletree, clamping-jaws extending laterally from the outer end of the trace-holder, and a hook located between the clamping-jaws and extending from the outer end of the body portion of the trace-holder.

812,391. HOG-TRAP. ALBERT AUCHLY, Montgomery, Mo. Filed Jan. 3, 1905. Serial No. 239,433.



Claim.—1. In a machine of the class described, the combination of sides, two parallel platform-strips pivoted at their forward ends, means for elevating their rear ends, sheet-metal covers for said strips, a strip between the parallel strips, means for pivoting the parallel strips to the strip between them at a point some distance from the front end thereof, a cross-piece fixed to the central strip in the rear of its pivotal point, two strips secured to the ends of said cross-piece adjacent to the outer edges of the parallel strips, rigid shields

fixed to the inner forward ends of the outer strips and projected upwardly and a crank-shaft having its central portion pivoted to the rear ends of the said central strip and the two outside strips and having its ends pivotally supported.

2. In a device of the class described, the combination of sides, two channel-bars secured to the inner faces of the rear ends of the sides, an arch connected to the sides, a trap-door slidingly mounted in the said channel-bars, a gravity-hook at the top of the trap-door to engage the under surface of the top of the arch when the trap-door is at its lower limit of movement and a gravity-hook mounted near the bottom of the trap-door to engage the top of the arch and support the trap-door when at its upper limit of movement, for the purposes stated.

3. In a device of the class described, the combination of sides, an arch at the rear of the sides for supporting them, two channel-bars secured to the inner faces of the sides in the rear of the arches, a trap-door vertically movable in said channel-bars, a gravity-hook mounted near the top of the trap-door projected through an opening therein and formed with a handle at its upper end, said hook having a shoulder designed to engage the under surface of the arch when the trap-door is at its lower limit to prevent upward movement of the trap-door, a hook near the bottom of the trap-door pivoted thereto and projected to an opening therein, said hook formed with a shoulder and handle, the handle on the rear face of the trap-door, said hook designed when the trap-door is elevated to engage the top of the arch and hold the trap-door in its elevated position.

4. In a device of the class described, the combination of sides, brackets secured to the sides near the front thereof and formed with dovetailed grooves open at their forward ends and a front having a cross-piece having projections with enlarged heads designed to enter the dovetailed grooves and to pivotally support the front and to prevent the sides from spreading.

5. In a device of the class described, the combination of sides, brackets secured to the inner faces of the front ends of the sides and formed with dovetailed grooves open at their forward ends, a cross-piece formed with rounded projections at its ends and enlarged heads on the rounded projections, said projections and heads designed to enter the dovetailed grooves and to pivotally support the cross-piece and to prevent the sides from spreading, pins passed through the brackets in front of the rounded ends, and a front secured to the said cross-piece.

6. In a device of the class described, the combination of sides, a cross-piece pivotally supported at the forward ends of the sides, two metal tubes secured to the cross-piece, two metal arches having said tubes passed through them, the arches projecting in front of the tubes, said arches formed with extensions at their ends and two guide-boards bolted to the said extensions with their central portions spaced apart.

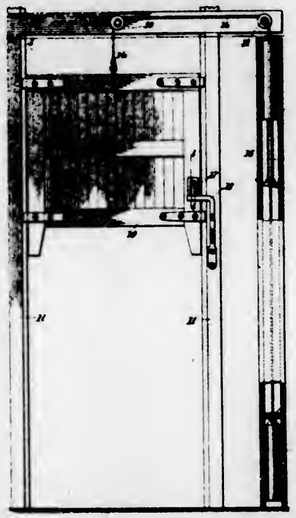
7. In a device of the class described, the combination of sides, a front having a central vertically-arranged opening, a platform, means for tilting the rear end of the platform upwardly and two arched metal strips secured to the sides near the top thereof and board secured to the under surface of said arched strips to prevent an animal on the tilted platform from backing up out of the top of the frame.

812,392. CUSHIONING APPARATUS FOR ELEVATOR-SHAFT GATES. WILLIAM BARDSLEY, Kearney, N. J. Filed Mar. 28, 1905. Serial No. 252,471.

Claim.—1. A vertically-movable gate, and a counterbalance-weight therefor, said weight being connected with the gate by a flexible connection and arranged to move vertically, combined with a cushioning apparatus for coöperation with said flexible connection and comprising a vertically-arranged cylinder and checking-piston therein and one of which constitutes a movable member, said gate and flexible connection being adapted to have a greater extent of movement than said movable member and to move independently of the same during a part of the closing movement of said gate and to effect the movement of said movable member to create the cushion during another portion of such closing movement; substantially as set forth.

2. A vertically-movable gate, and a counterbalance-weight therefor, said weight being connected with the gate by a flexible connection and arranged to move vertically, combined with a cushioning apparatus for coöperation with said flexible connection and comprising a vertically-arranged cylinder and checking-piston therein through both of which said flexible connection freely passes and one of which is movable upon the other to create the cushion, and means carried by said flexible connection for engaging said movable mem-

ber only during a portion of the closing movement of the gate and moving the same to create the cushion; substantially as set forth.



3. A gate and a counterbalance-weight therefor, said weight being connected with the gate by a flexible connection and arranged to move vertically, combined with a cushioning apparatus through which said flexible connection passes and which comprises the fixed cylinder having the central guiding-tube open at both ends, and hollow piston-rod carrying the piston and encompassing said tube, said piston-rod normally extending from said cylinder in position to be struck, upon the closing of the gate, by a part carried by said flexible connection, for moving said piston-rod and piston within said cylinder and creating the cushion; substantially as set forth.

4. A vertically-movable gate, and a counterbalance-weight therefor, said weight being connected with the gate by a flexible connection and arranged to move vertically, combined with a cushioning apparatus for coöperation with said flexible connection and comprising the vertically-arranged cylinder having the central guiding-tube open at both ends, and the hollow piston-rod carrying the piston and encompassing said tube, one of said parts being movable and the other fixed and said flexible connection being freely extended downwardly through said cylinder, piston and rod and provided with means for engaging said movable part only during a portion of the closing movement of the gate and moving the same to create the cushion; substantially as set forth.

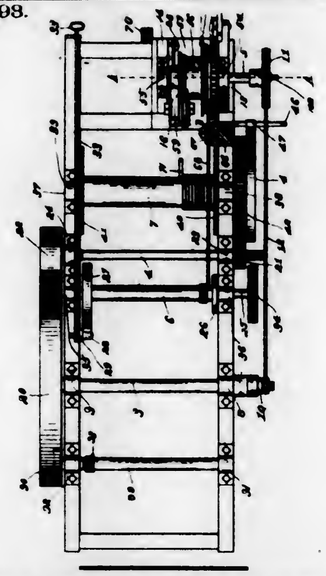
812,393. WELL-DRILLING MACHINE. DAVID L. BAUGHER, Paola, Kans., assignor of one-half to John P. Thayer, Paola, Kans. Filed Mar. 8, 1905. Serial No. 249,120.

Claim.—1. In a well-drilling machine, the combination of a supporting-frame, an oscillating shaft mounted thereon, a segmental arm fixed upon one end of said shaft, a crank-arm fixed upon the opposite end, a drum and a ratchet-rim loosely supported on said shaft, an arm 10, a shaft 3, and a ratchet-lever carrying a pawl which engages said ratchet-rim, substantially as described.

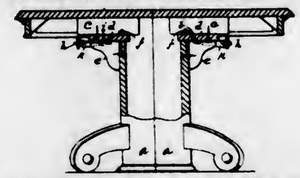
2. In a well-drilling machine, a supporting-frame, an oscillating shaft supported on the frame, a ratchet-rim carried by said shaft, a drum, a segmental arm fixed upon one end of said shaft, a crank-arm fixed upon the opposite end, a shaft 3, an arm 10 fixed thereon, a rope connecting said segmental arm to said arm 10, a derrick, a spiral spring connected to the derrick, and a rope-clamp attached to said spring, substantially as described.

3. In a well-drilling machine a supporting-frame, an oscillating shaft, a segmental arm rigid to one end thereof, and a crank-arm rigid to the opposite end, a drum mounted on said shaft, a ratchet-rim carried by the drum, a concave-faced pulley carried by the crank-arm, a yoke adapted to prevent disengagement of a rope from said pulley, a rocking-lever, pawls carried by the lever, said pawls adapted to alternately engage the ratchet-rim, substantially as described.

812,393.



812,394. PEDESTAL-TABLE. THADDEUS C. BEACH, St. Johns, Mich. Filed Mar. 3, 1905. Serial No. 248,080.



Claim.—1. Adjusting mechanism comprising two adjacent structures, one of which is stationary, and the other of which is movable at one extremity thereof, having a wedge-shaped recess therebetween, a wedge to move longitudinally in said recess, a bolt located in said recess upon which said wedge is mounted, and a nut upon said bolt to actuate said wedge, whereby the movable structure is actuated.

2. Adjusting mechanism comprising two adjacent structures, one of which is stationary and the other of which is movable at one extremity thereof, provided with a wedge-shaped recess therebetween, a stationary bolt located in said recess, a wedge to move longitudinally of the bolt in the recess, and a nut upon the bolt to actuate said wedge.

3. Adjusting mechanism comprising two adjacent structures, one of which is stationary and the other of which is movable at one extremity thereof, having a wedge-shaped recess therebetween, a stationary bolt located in said recess, a wedge to move longitudinally of the bolt within the recess, and a nut upon said bolt to actuate the wedge, said nut engaged with the wedge to actuate the wedge in opposite directions.

4. Adjusting mechanism comprising two adjacent constructions having a recess therebetween, a bolt located in said recess, a wedge movable longitudinally of the bolt in the recess, and a nut upon said bolt to actuate the wedge, said nut provided with a flange and the wedge recessed to receive the flange of the nut whereby the wedge may be actuated by the nut in opposite directions.

5. In an extension-table the combination of separable top sections, separable pedestal-sections, transverse plates uniting the pedestal-sections with the top sections, exterior brackets upon the pedestal-sections, each of said transverse plates, and its companion bracket constructed with a wedge-shaped recess therebetween, a stationary bolt located in said recess, a wedge movable longitudinally of the bolt within the recess between the corresponding transverse plate and its companion bracket, and a nut upon the bolt to actuate the wedge.

6. An adjusting device for the purpose described comprising in combination a bolt, a wedge carried upon said bolt and movable longitudinally of the bolt, and a nut upon said bolt to actuate the wedge, said nut engaged with the wedge to actuate the wedge in opposite directions upon the bolt.

7. The combination of a bolt, a wedge movable longitudinally of the bolt, a nut upon the bolt to actuate the wedge, said nut provided with a flange, and the wedge constructed with a recess to receive the flange of the nut whereby the wedge may be actuated by the nut in opposite directions.

8. In an extension-table the combination of separable pedestal-sections, exterior brackets upon the pedestal-sections, respectively, a plate rigidly secured to each of said sections, each of said brackets and its companion plate formed with a wedge-shaped recess therebetween, a stationary bolt located in said recess, a wedge movable longitudinally of the bolt within the recess, and a nut upon the bolt to actuate the wedge, whereby the lower extremities of the pedestal-sections may be forced inward, the one toward the other.

9. In an extension-table the combination of separable pedestal-sections movable at their lower extremities each provided with a bracket and with a stationary plate above the corresponding bracket, a stationary bolt extending between each bracket and its companion plate, a wedge movable longitudinally of the bolt between each bracket and its companion plate, and means to actuate the wedge, whereby the lower extremities of the sections will be forced inward, the one toward the other.

10. In an extension-table the combination of separable pedestal-sections, brackets secured to the said sections, a stationary plate rigidly secured upon the top of each of said sections, each of said brackets and its companion plate formed with a wedge-shaped recess therebetween, a stationary bolt located in the recess formed with a hook at its inner end engaged with the corresponding plate, a wedge carried on the opposite end of said bolt, and means to actuate the wedge whereby the lower extremity of said sections will be forced inward, the one toward the other.

812,395. PORTABLE DENTAL FURNACE. FREDERICK S. BELTHA, Brookline, Mass. Filed June 2, 1904. Renewed Jan. 9, 1906. Serial No. 295,256.

Claim.—1. In a portable dental furnace, a metallic muffle having an opea mouth, and a shell-like outer casing inclosing the muffle with a clearance between them and entirely open at its rear end and bottom, the muffle being attached to and supported by the closed front end of the casing.

2. In a portable dental furnace, a metallic muffle having an open mouth, a thin, shell-like casing inclosing the muffle with a clearance between them and entirely open at its rear end and bottom, the front end of the casing having an opening to receive the muffle, retaining-ears on said end of the casing to frictionally engage and hold the muffle in place within the casing, and a handle attached to the latter.

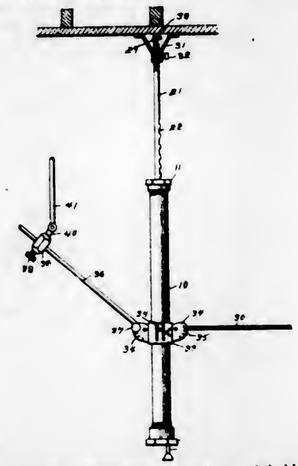
3. In a portable dental furnace, a metallic muffle having an open mouth, a metallic, shell-like casing inclosing the muffle with a clearance between them for the circulation of flame, the casing being entirely open at its rear end and bottom and having a closed front end through which the muffle is extended and to which it is attached, a shield projecting beyond the mouth of the muffle at the bottom thereof, and a handle attached to the casing.

4. In a portable dental furnace, a metallic muffle having an open mouth, a casing inclosing the muffle with a clearance between them for the circulation of flame, the casing being open at its rear end and bottom to expose the muffle to the direct flame and having a closed front end through which the muffle is extended and to which it is attached, the closed end of the casing being laterally extended beyond the perimeter of the muffle, and ears on said closed end of the casing to frictionally engage and retain the muffle in position in the casing.

5. In a portable dental furnace, a metallic muffle having an open mouth, a casing inclosing the muffle with a clearance between them for the circulation of flame, the casing being open at its rear end and bottom and having a closed front end through which the muffle is extended and to which it is attached, a shield projecting beyond the mouth of the muffle at the bottom thereof, ears on the closed end of the casing to frictionally engage and hold the muffle in position in the casing, and an elongated handle secured to the casing.

6. In a portable dental furnace, a metallic muffle having an open mouth, a metallic, semicylindrical outer casing inclosing the muffle with a clearance between them and having an opening in its top, the rear end and bottom of the casing being open and its front end closed, means to frictionally and detachably connect the muffle and the closed end of the casing, and an elongated handle secured to the latter.

812,396. DISPLAY-RACK. FRANK E. BEWYER, Newton, Iowa. Filed July 19, 1904. Serial No. 217,190.



Claim.—1. The combination of a rod, a rack-holder slidingly mounted on the rod, a ball-retainer secured at one end of the rack-holder, balls therein engaging the rod, a ball-retainer secured at one end of the rod, and balls therein engaging the rack-holder.

2. The combination of a supporting-rod, a tubular standard having one end of the rod slidingly mounted therein, a ball-retainer secured at one end on the inside of the tubular standard, balls therein engaging the rod, a second ball-retainer slidingly mounted inside of the tubular standard and fixed to the rod, balls therein engaging the tubular standard and a gripping device inside of the tubular standard engaging the rod.

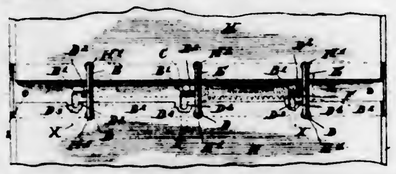
3. The combination of a notched supporting-rod, a tubular standard slidingly mounted on the supporting-rod, a gripping-plate pivotally mounted within the tubular standard having an opening therein through which the supporting-rod is passed, said plate in one position engaging the notches of the supporting-rod and in another position permitting the supporting-rod to freely slide through the opening thereof, a grip-actuating rod within the tubular standard and projecting beyond it operatively connected with the gripping-plate and a spring normally holding the grip-actuating rod to position with the gripping-plate in engagement with one of the notches of the supporting-rod.

4. The combination of a notched supporting-rod, a tubular standard having the rod slidingly mounted therein, a ball-retainer secured to one end of the tubular standard, balls therein engaging the rod, a support connected with the ball-retainer, a gripping-plate, having a central opening to admit the rod, pivotally mounted at one edge in said support and a grip-actuating rod connected with the opposite edge of the gripping-plate and projected beyond the tubular standard.

5. The combination of a notched supporting-rod, a tubular standard encircling one end of the notched rod, screw-caps on the tubular standard, a ball-retainer secured to one end of the tubular standard, balls therein engaging the rod, a gripping-plate having an opening therein to receive the rod pivotally mounted at one edge on said ball-retainer, a link connected to the opposite edge of the gripping-plate, a grip-actuating rod slidingly mounted in the tubular standard pivoted to said link, a handle on the opposite end of said grip-actuating rod projected through the cap, a spring normally holding the grip-actuating rod in position with the gripping-plate engaging the notched supporting-rod.

812,397. BINDER FOR LOOSE LEAVES OF BOOKS. JACOB P. BOEHNER, Freeport, Ill. Filed Sept. 6, 1904. Serial No. 223,562.

Claim.—1. In a binder for loose leaves of books, in combination, a back plate having a plurality of L-shaped slots therein and transverse lugs thereon, the latter provided with concentric circular bearings extending therethrough, a longitudinally-slidable rock-shaft mounted in the bearings in the lugs on the back plate, semirings, corresponding in number with the slots in the back plate and rigidly secured, by one end of each thereof, to the rock-shaft, and projecting transversely therefrom and parallel to each other through the slots in the back plate, and adapted to slide in the vertical arms of such slots and to be rocked over into and detained in their horizontal arms, semirings, the counterparts of and corresponding in number with the hereinbefore-mentioned semirings and fast mounted, on the back plate, parallel to each other and adjacent to the outer ends of the vertical arms of the slots therein, and a spring normally acting, through the longitudinally-slidable rock-shaft, to maintain the movable semirings in operative relation to and in engagement with their counterpart stationary semirings, substantially as described.

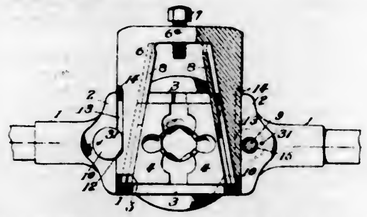


2. In a binder for loose leaves of books, in combination, a trough-like back piece, preferably D-shaped in cross-section, a back plate fast thereto and having a plurality of L-shaped slots therein and transverse lugs thereon, the latter provided with concentric circular bearings extending therethrough, a longitudinally-slidable rock-shaft mounted in the bearings in the lugs on the back plate, semirings, corresponding in number with the slots in the back plate and rigidly secured, by one end of each thereof, to the rock-shaft, and projecting transversely therefrom and parallel to each other through the slots in the back plate, and adapted to slide in the vertical arms of such slots and to be rocked over into and detained in their horizontal arms, semirings, the counterparts of and corresponding in number with the hereinbefore-mentioned semirings and fast mounted, on the back plate, parallel to each other and adjacent to the outer ends of the vertical arms of the slots therein, and a spring normally acting, through the longitudinally-slidable rock-shaft, to maintain the movable semirings in operative relation to and engagement with their counterpart stationary semirings, substantially as described.

3. In a binder for loose leaves of books, in combination, a trough-like back piece A, preferably D-shaped in cross-section, a back plate B fast thereto and having a plurality of L-shaped slots B′ therein and transverse lugs B^2 thereon, the latter provided with concentric circular bearings B^3 extending therethrough, a longitudinally-slidable rock-shaft C, mounted in the bearings B^3 in the lugs B^2 on the back plate B, semirings D, corresponding in number with the slots B′ in the back plate B and rigidly secured by one end D′ of each thereof, to the rock-shaft C, and projecting transversely therefrom and parallel to each other through the slots B′ in the back plate B, and adapted to slide in the vertical arms D^2 of such slots B′ and to be rocked over into and to be detained in their horizontal arms D^2, semirings E, the counterparts of and corresponding in number with the semirings D and fast mounted, on the back plate B, parallel to each other and adjacent to the outer ends of the vertical arms D^2 of the slots B′ therein, a spring encircling the rock-shaft C and serving therethrough to maintain the movable semirings D in operative relation to and engagement with their counterpart stationary semirings E, and covers G, connected with the back of the holder, substantially as described.

812,398. **ADJUSTABLE DIE-STOCK.** BRADFORD BORDEN, Warren, Ohio, assignor, by mesne assignments, to The Borden Company, Warren, Ohio, a Corporation of Ohio. Filed Jan. 4, 1905. Serial No. 239,689.

Claim.—1. A die-stock comprising an open-front housing having end walls, sectional dies within the housing between such walls, a free sliding adjuster filling the spaces between the dies and the end walls for moving the former toward and away from each other, said adjuster having stops on its front face adjacent its edges, and means for limiting the extreme movements of the adjuster and holding the latter and the dies as against lateral displacement during the cutting operation, such means comprising spring-pressed bolts mounted in the housing and having their heads overlapping the side edges of the adjuster, and means for simultaneously drawing the heads of said bolts tight against the adjuster.



2. A die-stock comprising an open-front housing having opposite end walls, sectional dies between such end walls having grooves in their front faces, a free sliding adjuster having side members filling the spaces between the dies and the end walls for moving the former toward and away from each other, said side members having grooves in their outer faces and tongues on their inner faces fitting the grooves of said dies, spring-pressed bolts mounted in said end walls and having their heads extended into said grooves of said side members, and means for simultaneously binding the heads of both bolts against said side members.

3. A die-stock comprising a housing having end walls, sectional dies within the housing, a free sliding adjuster for filling the spaces between the dies and said end walls and for effecting the movements of the dies toward and away from each other, a centering device, means for actuating such centering device, means mounted in the housing for limiting the extreme movements of the adjuster and preventing the lateral displacement thereof, and means for controlling such latter means operated simultaneously with and by the means for actuating the centering device.

4. A die-stock comprising a housing having end walls, sectional dies within the housing, a free sliding adjuster for filling the spaces between the dies and said end walls and for effecting the movements of the dies toward and away from each other, a centering device, means for actuating such centering device, means mounted in the housing for preventing the lateral displacement of the adjuster, and means for controlling such latter means operated simultaneously with and by the means for actuating the centering device.

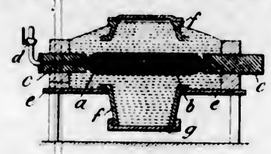
5. A die-stock comprising a housing having end walls, sectional dies within the housing, a free sliding adjuster for filling the spaces between the dies and said end walls and for effecting the movements of the dies toward and away from each other, a centering device, means for actuating such centering device, spring-pressed bolts mounted in said housing having their heads over-lapping portions of said adjuster, stops on the latter with which said heads engage for limiting the extreme movements of the adjuster, said bolts also preventing the lateral displacement of the latter, and means for drawing said bolts against the adjuster, such means being controlled by the actuating means of the centering device.

6. A die-stock comprising a housing, sectional dies within the latter, a free sliding adjuster having side members filling the spaces between the dies and said end walls for effecting the movements of the dies toward and away from each other, said side members having grooves in their front faces, spring-pressed bolts extended through said housing and having their heads projecting into said grooves, retaining-pins passed through said bolts, adjusting-plates having beveled ends engaging said retaining-pins for moving said bolts as against the spring-pressure thereon, a centering device, and a common means for simultaneously actuating the latter and said adjusting-plates.

7. The combination with the housing, the sectional dies and the adjuster for the latter, of the spring-pressed bolts passed transversely through the housing having their heads overlapping the edges of the adjuster, retaining-pins passed through the bolts, adjusting-plates having slotted beveled ends engaging said pins, and also having lugs, a centering device having two sliding jaws formed with lugs, and an actuating-plate having two sets of cam-slots to receive all of said lugs, whereby as the centering-jaws are moved toward each other the adjusting-plates will be forced between the housing and said retaining-pins.

8. The combination with the housing, the sectional dies and the adjuster for the latter, of the spring-pressed bolts passed transversely through the housing having their heads overlapping the edges of the adjuster, a centering device having opposite jaws, adjusting-plates for engaging said bolts and moving them into engagement with the adjuster, said adjusting-plates being capable of being moved to a greater extent than is required to so move said bolts, and a controlling-plate for simultaneously moving said jaws and adjusting-plates, the latter permitting the former to be adjusted to accommodate bolts or pipes of different sizes.

812,399. **MANUFACTURE OF SILICA GLASS.** JAMES P. BOTTOMLEY, Walkend, ROBERT S. HUTTON, Manchester, and ARTHUR PAGET, North Cray, England. Filed Mar. 21, 1905. Serial No. 251,321.



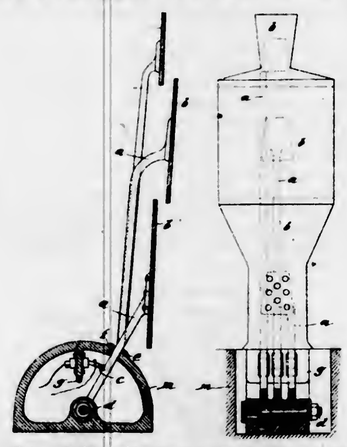
Claim.—1. The improved process of manufacturing articles of silica glass which consists in heating the crude material by means of the heat generated by a resistance such as carbon placed in an electric circuit until the requisite mass is in a plastic condition, then while still plastic shaping the mass by internal blowing.

2. The improved process of manufacturing articles of silica glass which consists in heating the crude material by means of the heat generated by a resistance such as carbon placed in an electric circuit and out of contact with the material to be fused until the requisite mass is in a plastic condition, then while still plastic shaping the mass by internal blowing.

3. The improved process of manufacturing articles of silica glass which consists in fusing the crude material by means of the heat generated by a hollow perforated resistance-core placed in an electric circuit, then securing the fused mass to the extremities of the core and then passing compressed air or gas through said core so as to effect the shaping of the fused mass *in situ*.

4. The improved process of manufacturing articles of silica glass which consists in fusing the crude material by means of the heat generated by a resistance placed in an electric circuit, then securing the extremities of the fused mass, then blowing the fused mass and effecting the shaping *in situ*.

812,400. **INDICATING-TARGET.** RENÉ M. V. BRENER, Schaerbeeck-Brussels, Belgium. Filed July 25, 1904. Serial No. 218,143.

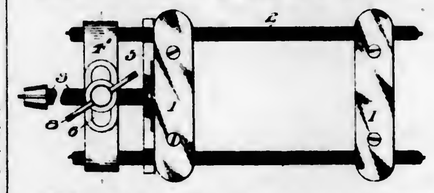


Claim.—1. In combination, a series of separate parts of the target all supported on distinct levers, a pin-support for the same at the basis of a case, a slot in the said case directed toward the line of firing, one part of said slot forming a means of support of the target-arms at an inclined position of rest, the other part of the said slot forming an upward check to the recoil of the said targets, and means for making electrical contact when the targets are driven back.

2. In combination, a series of separate parts of the target all held in a position of rest with their weight passing beyond their supports toward the firing direction, a pin-support for the same at the basis of a case, a contact-piece upon the outer face of each bar, and two spring-pressed pistons, adapted to close together under the recoil of the beam, each of said pistons having differential springs to maintain an elongated contact.

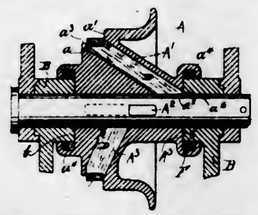
3. In combination, a series of separate parts of the target, all held in a position of rest with their weight passing beyond their support toward the firing direction, and a counterbalance-weight extended toward the direction of firing to give an adjustable control to the resilience of the target-faces.

812,401. **WIRE-STRETCHING DEVICE.** WILLIAM BROAD, Aliquippa, Pa. Filed May 23, 1905. Serial No. 261,743.



Claim.—In a device of the character described, a vise-head formed in sections, one of said sections having an elongated hollow boss, the opening of the boss conforming to the contour of the boss, a second section having an elongated boss adapted to fit snugly within the opening of the first-named section, said boss having a centrally-threaded recess, a screw member engaging the threads of the recess, said screw member being provided with a head bearing against the first-named section and a presser-head operatively connected to one of the sections.

812,402. **LUBRICATING DEVICE FOR WHEELS AND AXLES.** GASTON A. BRONDER, Brooklyn, N. Y. Filed Apr. 29, 1903. Serial No. 154,765.



Claim.—1. The combination of an axle, a wheel thereon having ducts leading from an outer circumferential portion thereof to the bearing-surface on the axle, and extending from end to end of said surface and helically around the same, the ducts tapering from the bearing-surface to the said outer portions of the wheel, there being hoods extending from the hubs of the wheel, and wicks in the ducts and hoods.

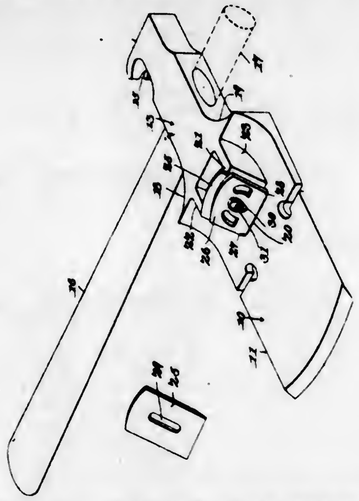
2. The combination of an axle, a wheel thereon having ducts leading from an outer circumferential portion thereof to the bearing-surface on the axle, and extending from end to end of said surface and helically around the same, the ducts tapering from the bearing-surface to the said outer portion, hoods extending from the hubs of the wheel, wicks in the ducts and hoods, a wick wrapped around the wheel covering the wicks in the ducts, a wiper bearing against the wrapped wick, and an oil-reservoir for the wiper.

812,403. **SHINGLING-HATCHET.** WILLIAM V. BROWN, Berwick, Canada. Filed Oct. 5, 1905. Serial No. 281,493.

Claim.—1. A hatchet constructed with one side face of the head portion and one side face of the blade portion in longitudinal alinement and with a transverse aperture intermediate the blade and the head portion, an inclined supporting-web extending from said aperture, a plane-bit bearing upon said web and extending through said aperture, a chip-breaker bearing upon said plane-bit and protruding into said aperture, and means for adjustably clamping said chip-breaker and plane-bit to said web.

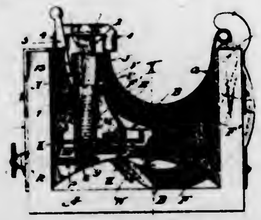
2. A hatchet constructed with one side face of the head portion and one side face of the blade portion in longitudinal alinement and with a transverse aperture intermediate the blade and the head portion, an inclined supporting-web extending from said aperture, a plane-bit bearing upon said web, and extending through said aper-

ture, a chip-breaker bearing upon said plane-bit and protruding into said aperture and formed with laterally-extending shoulders bearing upon the hatchet-blade at the ends of the aperture.



3. A hatchet constructed with a relatively broad thin blade with parallel side edges and a contracted head portion whereby finger-grips are formed at the juncture of the head portion and blade, the head portion carrying a hammer-face and through which the handle is inserted and with one face of the head portion and one face of the blade in longitudinal alinement an aperture disposed transversely through the blade and an inclined web extending from said aperture at one side and merging into the head portion, a plane-bit bearing against said web and extending through said aperture, a chip-breaker bearing upon said plane-bit and protruding into said aperture, and means for adjustably clamping said plane-bit and chip-breaker upon said web.

812,404. EAVES-TROUGH CLAMP. GEORGE M. BUTLER and CHARLES G. BERINGER, Washburn, Ill. Filed Mar. 22, 1905. Serial No. 251,370.



Claim.—1. In an eaves-trough clamp, devices for receiving and holding one edge of an eaves-trough, a plurality of members of varying size below the same for receiving troughs of different sizes each of said members being employed only for the size of trough corresponding thereto and a clamping member for descending upon the opposite edge of the trough and holding it in place within the member designed for it.

2. In an eaves-trough clamp, devices for receiving and holding one edge of an eaves-trough, a member for receiving and supporting the trough for the purposes described, and a clamp at the opposite edge of the trough for holding the said trough, said member adapted to pass out of the way to be replaced by another member of a different size for the purposes described.

3. In an eaves-trough clamp, devices for receiving and holding in place one edge of an eaves-trough, a removable U-shaped member for receiving said trough, a clamp for crowding down and holding the trough in the said member, and means for supporting the member in its proper position.

4. In an eaves-trough clamp, devices for receiving and holding in place one edge of an eaves-trough, a removable member for receiving the trough and in which said trough fits, a clamp for holding the trough in place within the member, means for supporting the member in position, the means adapted to release the said members and engage others of different size.

5. In an eaves-trough clamp, a support, devices mounted thereon to receive and hold an edge of the trough, a member pivoted at one extremity on the support and adapted for the reception of the trough, a clamp for descending upon the opposite edge of the trough for forcing it into and holding it within the member, supporting means for sustaining the member at its free end but adapted to release the member, and a similar member of different size adapted for separate engagement with the supporting means for the purposes described.

6. In an eaves-trough clamp, a support, overhanging hooked devices for receiving one edge of the trough, a U-shaped member pivoted at one end to the support below the devices described, its other end adapted to be raised for receiving the trough, horizontally-adjusted means for supporting it in position for use, a clamp for descending upon the free edge of the trough for holding it within the member, and a second pivoted member of different size adapted for engagement with the horizontally-adjustable means for receiving a trough of different size, the clamp adapted also to sustain the different-sized troughs in place.

7. In an eaves-trough clamp, a support, hooked devices secured thereto for receiving one edge of the trough, a vertically-movable member for holding the trough, means for holding that member in rigid position for use, a vertically-movable clamp for bearing upon the opposite edge of the trough and means for releasing the clamp to permit it to rise to release the trough.

8. In an eaves-trough clamp, a support, devices for receiving and holding one edge of the trough, a plurality of trough-supporting members of different sizes, adjustable means for separately holding any one of the members in a raised position for use, an adjustable clamp for engaging the free edge of the trough, and means in connection with said clamp for holding it in engagement with the said trough.

9. In an eaves-trough clamp, a support, devices for receiving and holding one edge of the trough, a plurality of trough-supporting members of different sizes, adjustable means for separately holding any one of the members in raised position for use, an adjustable clamp for engaging the free edge of the trough, and means in connection with said clamp for holding it in engagement with the said trough, the latter means adapted to release said clamp to free the trough.

10. In an eaves-trough clamp, a support, means for holding one edge of the trough, a plurality of adjustable members of different sizes for separately holding the trough and an adjustable device for engaging any one of the said adjustable members for holding it in a fixed position and adapted for releasing the same, and a clamp carried on and moving with the said device for clamping the separate different-sized troughs.

11. In an eaves-trough clamp, a support, devices for holding one side of the trough, a clamp for holding the opposite side, a plurality of members of a different size each for supporting troughs corresponding in size and form thereto each being vertically adjustable to bring it to a height that will meet the bottom and fit the trough and support it for the purposes explained.

812,405. CARPET-STRETCHER. EUGENE S. CAROTHERS, Westpoint, Miss. Filed Mar. 14, 1905. Serial No. 250,064.

Claim.—1. In a carpet-stretcher, the combination of a clamp comprising jaws, means for clamping said jaws together, a plurality of flat springs carrying said jaws and tending to maintain them in open position, an operating means for said clamp provided with a plurality of cranks, and link connections between said cranks and flat springs, substantially as described.

2. In a carpet-stretcher, the combination of a clamp comprising jaws, means for clamping said jaws together, a plurality of resilient means connecting said jaws, an operating means for said clamp provided with a plurality of cranks, and link connections between said cranks and resilient means, substantially as described.

3. In a carpet-stretcher, the combination of a clamp comprising jaws, means for clamping said jaws together, a plurality of resilient means connecting said jaws, an operating means for said clamp provided with a plurality of cranks, common means for actuating said several cranks, and link connections between said cranks and resilient means, substantially as described.

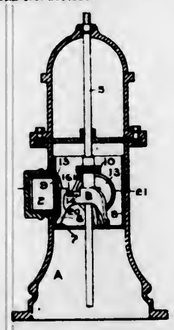
4. In a carpet-stretcher, the combination of a clamp comprising jaws, means for clamping said jaws together, a plurality of flat springs carrying said jaws and tending to maintain them in open position, an operating means for said clamp provided with a plurality of cranks, a common means for actuating said several cranks, and link connections between said cranks and flat springs, substantially as described.

812,406. CAN-OPENER. CHARLES COCHRAN, Plattsburg, N. Y. Filed June 30, 1905. Serial No. 267,830.

Claim.—1. A can-opener formed out of a single piece of wire and comprising a shank and a handle, said handle being formed by looping the wire upon itself and coiling it about the shank, the ends of the wire being bent downwardly to form a cutting-blade which is sharpened on one side throughout its entire length and is inclined relative to the shank so that various sizes of openings can be cut according to the amount the cutting-blade is pressed into the can, while the shank is formed with a series of zigzag portions which lie approximately in the plane of the handle, the free end of the shank being sharpened so as to provide a puncturing-point.

2. A can-opener formed out of a single piece of wire and comprising a shank one end of which is provided with a puncturing-point while the opposite end is provided with a handle formed by looping the wire upon itself and coiling it about the shank, the ends of the wire being bent downwardly to form a cutting-blade which is sharpened on one side throughout its entire length and inclined to the shank so that various sizes of openings can be cut according to the amount the cutting-blade is pressed into the can.

812,407. HYDRANT. ELIAS CRONSTEDT, St. Paul, Minn. Filed Nov. 3, 1903. Serial No. 179,667.



Claim.—1. In a hydrant, the combination with a casing formed with discharge-openings, of a rotatable spider arranged within the casing, a plurality of radially-slidable disk valves supported by the spider, valve-stems carried by said valves, and outwardly-extending retaining-keys removably supported in said valve-stems, for the purpose set forth.

2. In a hydrant, the combination with a casing formed with discharge-openings, of a rotatable spider arranged within said casing, disk valves slidably supported in said spider and curved to fit the inner wall of said hydrant, valve-stems carried by said valves and slidable in said spider, and retaining-keys extending through said valve-stems and outwardly from the sides thereof, for the purpose set forth.

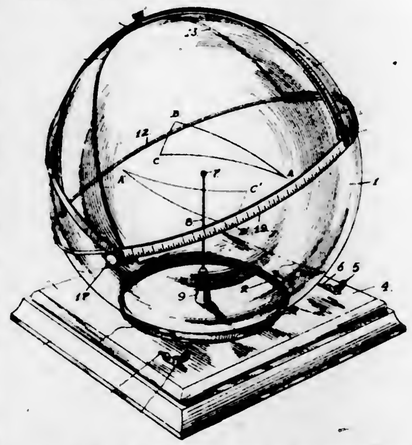
3. In a hydrant, the combination with its outer wall or casing provided with discharge-openings, of a rotatable spider arranged within said casing, a plurality of disk valves slidably supported in said spider and curved to fit the inner wall of said hydrant, said valves being each formed with a sharp outer edge, and means for rotating said spider.

4. In a hydrant, the combination with its outer wall or casing having discharge-openings, of a rotatable spider arranged within said casing, disk valves slidably supported in said spider and curved to fit the inner wall of said hydrant, keys holding said valves supported in said spider, said keys being each provided with an outer cutting edge, as and for the purpose set forth.

5. In a hydrant, the combination with its outer wall or casing having discharge-openings, and a valve-stem centrally supported in said hydrant, of a spider rotatably mounted upon said valve-stem, disk valves curved to fit the inner wall of said hydrant, valve-stems carried by said valves and slidable in said spider, and retaining-keys extending through said valve-stems, said keys each having an outer cutting edge, as and for the purpose set forth.

6. In a hydrant, the combination with its outer wall or casing having discharge-openings, of a bushing fitted in said casing and provided with openings registering with the discharge-openings, a spider rotatable within said bushing and resting upon a flange carried thereby, disk valves for said openings curved to fit the inner wall of said hydrant, inwardly-extending supporting-stems for said valves slidable in openings in said spider, retaining-keys extending through said stems, each of said keys being provided with an outer cutting edge, and means for rotating said spider.

812,408. EDUCATIONAL DEVICE FOR TEACHING SPHERICS. ROY E. DICKERSON, Boulder Creek, Cal. Filed Aug. 19, 1905. Serial No. 274,818.



Claim.—1. In an educational device for teaching spherics, a transparent, spherical board, having a center sight.

2. In an educational device for teaching spherics, a transparent, hollow, spherical board, having a center sight.

3. An educational device for teaching spherics, comprising a transparent, hollow, spherical board, having an open foot; a base on which the board is supported by its foot, and a clamping device engaging the foot for removably connecting the board with the base.

4. An educational device for teaching spherics, comprising a transparent, hollow, spherical board, having an open foot by which it is supported; a base with means for detachably connecting the board thereto, and means on the base for supporting accessory devices within the transparent, hollow board.

5. An educational device for teaching spherics, comprising a transparent, hollow, spherical board, having an open foot by which it is supported; a base with means for detachably connecting the board

thereto, and a post rising from the base through the open foot of the board, adapted to support accessory devices within said transparent hollow board.

Claim.—1. In a machine of the character described, the combination, with a sewing mechanism for making a double row of stitching, and a supporting-frame arm 2 of a feeding device arranged to

of the lower guide, said guides being arranged to act on the work in advance of the presser-foot and direct the same in a flat condition, and a cutting device, substantially as set forth.

pointed needle arranged above the bed-plate, a bobbin, a bobbin-case, a rotary loop-taker arranged below the bed-plate and containing the bobbin-case, a needle loop-seizing point on said loop-taker

thereto, and a post rising from the base through the open foot of the board, adapted to support accessory devices within said transparent hollow board.

6. An educational device for teaching spherics, comprising a transparent, hollow, spherical board, having an open foot by which it is supported; a base with means for detachably connecting the board thereto; a post rising from the base through the open foot of the board, and a center sight having a stem removably fitted to said post.

7. An educational device for teaching spherics, comprising a transparent, hollow spherical board, having an open foot by which it is supported; a base with means for detachably connecting the board thereto; a post rising from the base through the open foot of the board, and a figure form having a stem removably fitted to the post whereby said form is supported within said transparent hollow board.

8. In an educational device for teaching spherics, the combination of a transparent, hollow, spherical board, with a figure form removably fitted in its cavity in such relation to its wall as to be capable of being traced upon the surface of the board.

9. In an educational device for teaching spherics, and in combination with a spherical board, a spherical protractor adjustably fitted thereto and comprising a great-circle band, and suitable half-circle bands secured thereto.

10. In an educational device for teaching spherics, and in combination with a spherical board, a spherical protractor adjustably fitted thereto and comprising a great-circle band, and suitable half-circle bands secured thereto, said bands having scales and reading-arms for measuring angles and arcs.

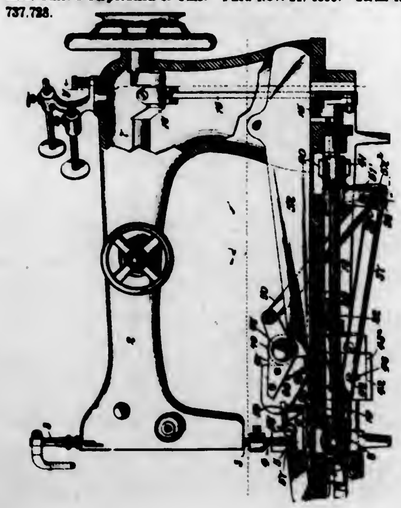
11. In an educational device for teaching spherics, the combination of a transparent spherical board with a spherical protractor adjustably fitted to its surface and comprising a great-circle band and suitable half-circle bands secured thereto, said bands having scales and reading-arms for measuring angles and arcs.

12. In an educational device for teaching spherics, the combination of a transparent spherical board having a center sight, and a spherical protractor adjustably fitted to the surface of said board and comprising a great-circle band and suitable half-circle bands secured thereto, said bands having scales and reading-arms for measuring angles and arcs.

13. In an educational device for teaching spherics, the combination of a transparent spherical board, and a concave transfer-plate adapted to be fitted to and to slide over the surface of said board.

14. In an educational device for teaching spherics, the combination of a transparent spherical board, and a concave transfer-plate adapted to be fitted to and to slide over the surface of said board, said transfer-plate being made of transparent material.

812,409. SEWING AND CUTTING MACHINE. JACOB DIEHL, Cleveland, Ohio, assignor to Standard Sewing Machine Company, Cleveland, Ohio, a Corporation of Ohio. Filed Nov. 21, 1890. Serial No. 737,738.



Claim.—1. In a machine of the character described, the combination, with a sewing mechanism for making a double row of stitching, and a supporting-frame arm 2, of a feeding device arranged to feed toward the base of said arm, a cutting device independent of the sewing mechanism located in the path of the work as it is fed from said sewing mechanism and in position to cut or split the same between the two rows of stitching so that the two parts of the work may pass one at each side of said arm, and means for actuating said feeding and cutting devices and causing them to alternately act upon the work.

2. In a machine of the character described, the combination, with a sewing mechanism for making a double row of stitching, and a supporting-frame arm 2, of a feeding device arranged to feed toward the base of said arm, a pivoted cutting device located between the sewing-point and the base of said arm in the path of the work as it is fed from the sewing mechanism and in position to cut or split the same between the two rows of stitching, and means for actuating said feeding and cutting devices and causing them to alternately act upon the work.

3. In a machine of the character described, the combination, with a sewing mechanism for making a double row of stitching, and a supporting-frame arm 2, of a feeding device arranged to feed toward the base of said arm, a pivoted cutting device supported upon the bed-plate of the machine in a position to cut or split the work between the two rows of stitching as it is fed from the sewing mechanism on a line extending from the stitching-point to the base of said arm, and means for actuating said feeding and cutting devices and causing them to alternately act upon the work.

4. In a machine of the character described, the combination, with a sewing mechanism for making a double row of stitching, of a feeding device, a cutting device independent of the sewing mechanism located in the path of the work as it is fed from said sewing mechanism and in a position to cut or split the same between the two rows of stitching, means for actuating said feeding and cutting devices and causing them to alternately act upon the work, comprising a transverse rock-shaft 34, and separate adjustable connections from said rock-shaft to the feeding and cutting devices, substantially as set forth.

5. In a machine of the character described, the combination, with a sewing mechanism for making a double row of stitching comprising a needle-actuating shaft and an overhanging support carrying the same, of a feeding device for feeding the material parallel with the said needle-shaft and support, a pivoted cutting device located in position to cut or split the work between the rows of stitching in a line parallel with the said needle-shaft support as the work is fed from the sewing mechanism, and a rock-shaft arranged transversely to said needle-actuating shaft and supported on the under side of the bed-plate of the machine, said rock-shaft having operative connections with the said feeding and cutting devices for actuating the same, substantially as set forth.

6. In a machine of the character described, the combination, with a sewing mechanism for making a double row of stitching, of a cutting device located in the path of the work as it is fed from the sewing mechanism and in position to cut or split the same between the two rows of stitching, means located at the rear of the cutting device at each side of the line of cut for spreading apart the severed portions of the work, and stretching the material evenly at the point of cutting and means for automatically feeding the work to the cutting device and forcing the same past the said separating means.

7. In a machine of the character described, the combination, with a sewing mechanism for making a double row of stitching, of a pivoted cutting device supported upon the bed-plate of the machine in a position to act upon the work between the two rows of stitching as it is fed from the sewing mechanism, actuating means for said cutting device comprising a connection extending through the said bed-plate, and two raised flanges extending in diverging directions from a point adjacent to the rear end of the cutting device and at opposite sides of said actuating connection.

8. In a machine of the character described, the combination, with a sewing mechanism for making a double row of stitching, of a cutting device located in the path of the work as it is fed from the sewing mechanism, two raised flanges extending in diverging directions from a point adjacent to the rear end of the cutting device and in line therewith, and means for automatically feeding the work to the cutter and forcing the same past the said diverging flanges, for the purpose set forth.

9. In a machine of the character described, the combination, with a sewing mechanism, of a guide for the work arranged below the same and having an upwardly-presented edge and a guide above the work having a downwardly-presented edge in line with the edge of the lower guide, said guides being arranged to act on the work in advance of the presser-foot and direct the same in a flat condition, and a cutting device, substantially as set forth.

10. In a machine of the character described, the combination of a sewing mechanism, two coöperating guides arranged to engage with the work at the upper and under sides thereof in advance of the presser-foot, the presser-foot, the presser-bar with which the upper of said guides is connected movably on a horizontal pivot allowing its outer end a vertical oscillation relative to the lower guide, and a cutting device, substantially as set forth.

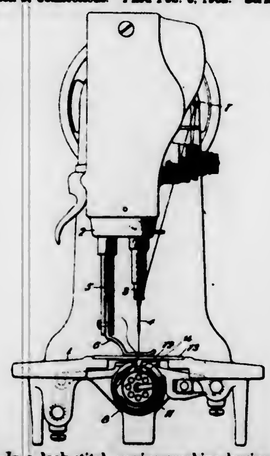
11. In a machine of the character described, the combination, with a presser-foot and a sewing mechanism, of two coöperating guides located in advance of said presser-foot and being arranged to coöperate with the work at the upper and under sides thereof, the upper guides being pivoted to the presser, a spring for normally holding said upper guide in operative position and a cutting mechanism situated at the rear of the presser-foot and having its cutting-line coinciding with the line of said guides.

12. In a sewing-machine of the character described, the combination of stitching mechanism comprising two needles, feeding devices, a cutter at the rear of the needles operating to sever the stitched work between the two rows of stitches, and means adjacent to the cutter for deflecting both of the stitched edges evenly in opposite directions away from the cutting-line, whereby the work is stretched at the point of cutting.

13. In a machine of the character described, the combination of a bed-plate, stitching mechanism comprising two needles, a power-shaft above the bed-plate for operating said needles, two rotary shafts beneath the bed-plate parallel with and operated by said power-shaft, two loopers one for each needle turning on an axis transverse to said rotary shafts and actuated by the latter, a rock-shaft arranged transversely to said two rotary shafts and actuated by one of them, a feeding device connected with said rock-shaft and actuated in directions transverse to the same, and a cutter also actuated by said rock-shaft and acting on a line between the needles and parallel with the said power-shaft.

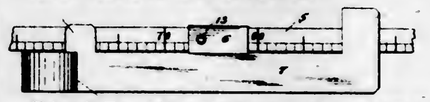
14. In a machine of the character described, the combination of a bed-plate, a main shaft arranged longitudinally of the machine, stitching mechanism comprising two needles arranged one at each side of the longitudinal line of the machine, two rotary shafts also arranged one at each side of said line and beneath the bed-plate, two loopers one for each needle turning in planes longitudinal of the machine and actuated respectively by said rotary shafts, a transverse rock-shaft beneath the bed-plate actuated by one of said rotary shafts, a feeding device acting longitudinally of the machine and operated by said rock-shaft, and a cutter acting on the longitudinal line of the machine and operated by said rock-shaft.

812,410. ROTARY LOOP-TAKER FOR SEWING-MACHINES. GEORGE H. DIMOND and WILBUR F. DIAL, Bridgeport, Conn., assignors to Wheeler & Wilson Manufacturing Company, Bridgeport, Conn., a Corporation of Connecticut. Filed Feb. 6, 1903. Serial No. 92,866.



Claim.—In a lock-stitch sewing-machine having a bed-plate, the combination of an independent take-up, a reciprocating eye-pointed needle arranged above the bed-plate, a bobbin, a bobbin-case, a rotary loop-taker arranged below the bed-plate and containing the bobbin-case, a needle loop-seizing point on said loop-taker, an adjacent guard extending in front of said point and overlapping it and adapted to prevent fouling of the needle and bobbin threads and loop-taker, and a needle loop-controller finger projecting rearwardly toward the said point to catch the loop of needle-thread as it draws off the point and carry it into the line of descent of the needle whence it slips off and is drawn up by the take-up to finish the stitch.

812,411. GAGE-READING DEVICE. GEORGE P. DOERR, Chicago, Ill. Filed Nov. 21, 1904. Serial No. 233,694.



Claim.—1. The combination with a gage-rod, of a reading device adjustably secured to said rod and having a lateral hook or the like for engagement with the inner side of the barrel at the center of the bung-hole transversely to the length of the barrel when said rod is inserted diagonally in a barrel or cask.

2. The combination with a gage-rod having a scale thereon, of a gage-reading device adjustably secured to said rod, said reading device having a lateral hook or the like extending across the side of said rod having the scale thereon and adapted to engage with the inner side of the barrel at the center of the bung-hole.

3. A gage-reading device comprising a sleeve or ferrule adapted to engage with a rod, a spring-strip connected with said sleeve, a lateral hook at one end of said spring-strip, a lateral catch or extension from said spring on the opposite side of said sleeve from said hook, and a ring or the like at the end of said spring for engagement with the finger.

4. A gage-reading device comprising a sleeve adapted to slidably engage with a gage-rod, a spring-strip secured to one side of said sleeve and having one end bent up and terminating in a lateral hook, said hook being adapted to engage with the upper edge of the rod and also with the inner side of the barrel to be gaged, the other end of said spring being provided with an extension or catch also adapted to engage with the upper edge of the rod, the end of said spring being bent for engagement with the finger.

5. In a gage-reading device for casks or barrels, the combination with a gage-rod, of a lateral scale-reading member adapted to engage laterally with the inner surface of a barrel at the center of the bung-hole when the rod is inserted in diagonal position, and means for adjustably securing said reading member on said rod, the arrangement being such that the gage-rod may be accurately read while it is inserted in the barrel, or the rod may be removed for reading without disturbing the gage-reading member.

6. A gage-reading device comprising a strip of suitable resilient material having a hook thereon, and means for adjustably securing said strip to a gage-rod.

812,412. DEVICE FOR COUPLING WIRE AND MANILA ROPE. HUGH DOWNS, Pittsburg, and WILLIAM C. WALLY, Etna, Pa. Filed June 21, 1905. Serial No. 266,251.

Claim.—In a device of the character described, a socket formed in two sections, one threaded within the other, one of said sections being provided with an eye, said socket being adapted to receive the end of a cable, means passing through the contacting portions of the sections and the cable to hold the sections against displacement one from the other, and to hold the cable within the socket, a second socket adapted to receive the end of a cable and a link connection between the sockets.

812,413. WIRE-ROPE PROTECTOR. HUGH DOWNS, Pittsburg, and WILLIAM C. WALLY, Etna, Pa. Filed June 27, 1905. Serial No. 267,186.

Claim.—1. In a wire-rope protector of the character described, a body portion having a double-tapered slot extending the full length thereof and adapted to fit over the cable; a double-tapered wedge to conform to the tapered slot adapted to fit in the latter, and means for locking said wedge in its seat; as, and for, the purpose set forth.

thereto, and a post rising from the base through the open foot of the board, adapted to support accessory devices within said transparent hollow board.

6. An educational device for teaching spherics, comprising a transparent, hollow, spherical board, having an open foot by which it is supported; a base with means for detachably connecting the board thereto; a post rising from the base through the open foot of the board, and a center sight having a stem removably fitted to said post.

7. An educational device for teaching spherics, comprising a transparent, hollow spherical board, having an open foot by which it is supported; a base with means for detachably connecting the board thereto; a post rising from the base through the open foot of the board, and a figure form having a stem removably fitted to the post whereby said form is supported within said transparent hollow board.

8. In an educational device for teaching spherics, the combination of a transparent, hollow, spherical board, with a figure form removably fitted in its cavity in such relation to its wall as to be capable of being traced upon the surface of the board.

9. In an educational device for teaching spherics, and in combination with a spherical board, a spherical protractor adjustably fitted thereto and comprising a great-circle band, and suitable half-circle bands secured thereto.

10. In an educational device for teaching spherics, and in combination with a spherical board, a spherical protractor adjustably fitted thereto and comprising a great-circle band, and suitable half-circle bands secured thereto, said bands having scales and reading-arms for measuring angles and arcs.

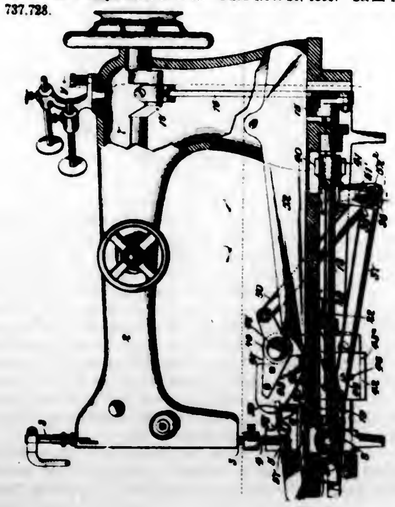
11. In an educational device for teaching spherics, the combination of a transparent spherical board with a spherical protractor adjustably fitted to its surface and comprising a great-circle band and suitable half-circle bands secured thereto, said bands having scales and reading-arms for measuring angles and arcs.

12. In an educational device for teaching spherics, the combination of a transparent spherical board having a center sight, and a spherical protractor adjustably fitted to the surface of said board and comprising a great-circle band and suitable half-circle bands secured thereto, said bands having scales and reading-arms for measuring angles and arcs.

13. In an educational device for teaching spherics, the combination of a transparent spherical board, and a concave transfer-plate adapted to be fitted to and to slide over the surface of said board.

14. In an educational device for teaching spherics, the combination of a transparent spherical board, and a concave transfer-plate adapted to be fitted to and to slide over the surface of said board, said transfer-plate being made of transparent material.

812,409. **SEWING AND CUTTING MACHINE.** JACOB DIEHL, Cleveland, Ohio, assignor to Standard Sewing Machine Company, Cleveland, Ohio, a Corporation of Ohio. Filed Nov. 21, 1899. Serial No. 737,728.



Claim.—1. In a machine of the character described, the combination, with a sewing mechanism for making a double row of stitching, and a supporting-frame arm 2, of a feeding device arranged to feed toward the base of said arm, a cutting device independent of the sewing mechanism located in the path of the work as it is fed from said sewing mechanism and in position to cut or split the same between the two rows of stitching so that the two parts of the work may pass one at each side of said arm, and means for actuating said feeding and cutting devices and causing them to alternately act upon the work.

2. In a machine of the character described, the combination, with a sewing mechanism for making a double row of stitching, and a supporting-frame arm 2, of a feeding device arranged to feed toward the base of said arm, a pivoted cutting device located between the sewing-point and the base of said arm in the path of the work as it is fed from the sewing mechanism and in position to cut or split the same between the two rows of stitching, and means for actuating said feeding and cutting devices and causing them to alternately act upon the work.

3. In a machine of the character described, the combination, with a sewing mechanism for making a double row of stitching, and a supporting-frame arm 2, of a feeding device arranged to feed toward the base of said arm, a pivoted cutting device supported upon the bed-plate of the machine in a position to cut or split the work between the two rows of stitching as it is fed from the sewing mechanism on a line extending from the stitching-point to the base of said arm, and means for actuating said feeding and cutting devices and causing them to alternately act upon the work.

4. In a machine of the character described, the combination, with a sewing mechanism for making a double row of stitching, of a feeding device, a cutting device independent of the sewing mechanism located in the path of the work as it is fed from said sewing mechanism and in a position to cut or split the same between the two rows of stitching, means for actuating said feeding and cutting devices and causing them to alternately act upon the work, comprising a transverse rock-shaft 34, and separate adjustable connections from said rock-shaft to the feeding and cutting devices, substantially as set forth.

5. In a machine of the character described, the combination, with a sewing mechanism for making a double row of stitching comprising a needle-actuating shaft and an overhanging support carrying the same, of a feeding device for feeding the material parallel with the said needle-shaft and support, a pivoted cutting device located in position to cut or split the work between the rows of stitching in a line parallel with the said needle-shaft support as the work is fed from the sewing mechanism, and a rock-shaft arranged transversely to said needle-actuating shaft and supported on the under side of the bed-plate of the machine, said rock-shaft having operative connections with the said feeding and cutting devices for actuating the same, substantially as set forth.

6. In a machine of the character described, the combination, with a sewing mechanism for making a double row of stitching, of a cutting device located in the path of the work as it is fed from the sewing mechanism and in position to cut or split the same between the two rows of stitching, means located at the rear of the cutting device at each side of the line of cut for spreading apart the severed portions of the work, and stretching the material evenly at the point of cutting and means for automatically feeding the work to the cutting device and forcing the same past the said separating means.

7. In a machine of the character described, the combination, with a sewing mechanism for making a double row of stitching, of a pivoted cutting device supported upon the bed-plate of the machine in a position to act upon the work between the two rows of stitching as it is fed from the sewing mechanism, actuating means for said cutting device comprising a connection extending through the said bed-plate, and two raised flanges extending in diverging directions from a point adjacent to the rear end of the cutting device and at opposite sides of said actuating connection.

8. In a machine of the character described, the combination, with a sewing mechanism for making a double row of stitching, of a cutting device located in the path of the work as it is fed from the sewing mechanism, two raised flanges extending in diverging directions from a point adjacent to the rear end of the cutting device and in line therewith, and means for automatically feeding the work to the cutter and forcing the same past the said diverging flanges, for the purpose set forth.

9. In a machine of the character described, the combination, with a sewing mechanism, of a guide for the work arranged below the same and having an upwardly-presented edge and a guide above the work having a downwardly-presented edge in line with the edge

of the lower guide, said guides being arranged to act on the work in advance of the presser-foot and direct the same in a flat condition, and a cutting device, substantially as set forth.

10. In a machine of the character described, the combination of a sewing mechanism, two coöperating guides arranged to engage with the work at the upper and under sides thereof in advance of the presser-foot, the presser-foot, the presser-bar with which the upper of said guides is connected movably on a horizontal pivot allowing its outer end a vertical oscillation relative to the lower guide, and a cutting device, substantially as set forth.

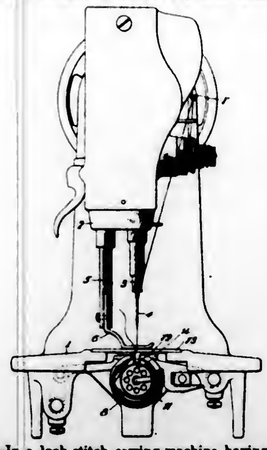
11. In a machine of the character described, the combination, with a presser-foot and a sewing mechanism, of two coöperating guides located in advance of said presser-foot and being arranged to coöperate with the work at the upper and under sides thereof, the upper guides being pivoted to the presser, a spring for normally holding said upper guide in operative position and a cutting mechanism situated at the rear of the presser-foot and having its cutting-line coinciding with the line of said guides.

12. In a sewing-machine of the character described, the combination of stitching mechanism comprising two needles, feeding devices, a cutter at the rear of the needles operating to sever the stitched work between the two rows of stitches, and means adjacent to the cutter for deflecting both of the stitched edges evenly in opposite directions away from the cutting-line, whereby the work is stretched at the point of cutting.

13. In a machine of the character described, the combination of a bed-plate, stitching mechanism comprising two needles, a power-shaft above the bed-plate for operating said needles, two rotary shafts beneath the bed-plate parallel with and operated by said power-shaft, two loopers one for each needle turning on an axis transverse to said rotary shafts and actuated by the latter, a rock-shaft arranged transversely to said two rotary shafts and actuated by one of them, a feeding device connected with said rock-shaft and actuated in directions transverse to the same, and a cutter also actuated by said rock-shaft and acting on a line between the needles and parallel with the said power-shaft.

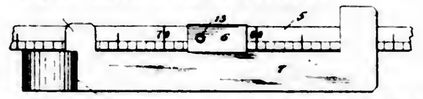
14. In a machine of the character described, the combination of a bed-plate, a main shaft arranged longitudinally of the machine, stitching mechanism comprising two needles arranged one at each side of the longitudinal line of the machine, two rotary shafts also arranged one at each side of said line and beneath the bed-plate, two loopers one for each needle turning in planes longitudinal of the machine and actuated respectively by said rotary shafts, a transverse rock-shaft beneath the bed-plate actuated by one of said rotary shafts, a feeding device acting longitudinally of the machine and operated by said rock-shaft, and a cutter acting on the longitudinal line of the machine and operated by said rock-shaft.

812,410. **ROTARY LOOP-TAKER FOR SEWING-MACHINES.** GEORGE H. DIMOND and WILBUR F. DIAL, Bridgeport, Conn., assignors to Wheeler & Wilson Manufacturing Company, Bridgeport, Conn., a Corporation of Connecticut. Filed Feb. 6, 1903. Serial No. 92,866.



Claim.—In a lock-stitch sewing-machine having a bed-plate, the combination of an independent take-up, a reciprocating eye-pointed needle arranged above the bed-plate, a bobbin, a bobbin-case, a rotary loop-taker arranged below the bed-plate and containing the bobbin-case, a needle loop-seizing point on said loop-taker, an adjacent guard extending in front of said point and overlapping it and adapted to prevent fouling of the needle and bobbin threads and loop-taker, and a needle loop-controller finger projecting rearwardly toward the said point to catch the loop of needle-thread as it draws off the point and carry it into the line of descent of the needle whence it slips off and is drawn up by the take-up to finish the stitch.

812,411. **GAGE-READING DEVICE.** GEORGE P. DOREN, Chicago, Ill. Filed Nov. 21, 1904. Serial No. 233,684.



Claim.—1. The combination with a gage-rod, of a reading device adjustably secured to said rod and having a lateral hook or the like for engagement with the inner side of the barrel at the center of the bung-hole transversely to the length of the barrel when said rod is inserted diagonally in a barrel or cask.

2. The combination with a gage-rod having a scale thereon, of a gage-reading device adjustably secured to said rod, said reading device having a lateral hook or the like extending across the side of said rod having the scale thereon and adapted to engage with the inner side of the barrel at the center of the bung-hole.

3. A gage-reading device comprising a sleeve or ferrule adapted to engage with a rod, a spring-strip connected with said sleeve, a lateral hook at one end of said spring-strip, a lateral catch or extension from said spring on the opposite side of said sleeve from said hook, and a ring or the like at the end of said spring for engagement with the finger.

4. A gage-reading device comprising a sleeve adapted to slidably engage with a gage-rod, a spring-strip secured to one side of said sleeve and having one end bent up and terminating in a lateral hook, said hook being adapted to engage with the upper edge of the rod and also with the inner side of the barrel to be gaged, the other end of said spring being provided with an extension or catch also adapted to engage with the upper edge of the rod, the end of said spring being bent for engagement with the finger.

5. In a gage-reading device for casks or barrels, the combination with a gage-rod, of a lateral scale-reading member adapted to engage laterally with the inner surface of a barrel at the center of the bung-hole when the rod is inserted in diagonal position, and means for adjustably securing said reading member on said rod, the arrangement being such that the gage-rod may be accurately read while it is inserted in the barrel, or the rod may be removed for reading without disturbing the gage-reading member.

6. A gage-reading device comprising a strip of suitable resilient material having a hook thereon, and means for adjustably securing said strip to a gage-rod.

812,412. **DEVICE FOR COUPLING WIRE AND MANILA ROPE.** HUGH DOWNS, Pittsburg, and WILLIAM C. WALLY, Etna, Pa. Filed June 21, 1905. Serial No. 266,251.

Claim.—In a device of the character described, a socket formed in two sections, one threaded within the other, one of said sections being provided with an eye, said socket being adapted to receive the end of a cable, means passing through the contacting portions of the sections and the cable to hold the sections against displacement one from the other, and to hold the cable within the socket, a second socket adapted to receive the end of a cable and a link connection between the sockets.

812,413. **WIRE-ROPE PROTECTOR.** HUGH DOWNS, Pittsburg, and WILLIAM C. WALLY, Etna, Pa. Filed June 27, 1905. Serial No. 267,126.

Claim.—1. In a wire-rope protector of the character described, a body portion having a double-tapered slot extending the full length thereof and adapted to fit over the cable; a double-tapered wedge to conform to the tapered slot adapted to fit in the latter, and means for locking said wedge in its seat; as, and for, the purpose set forth.

2. In a wire-rope protector of the character described,

2. In a wire-rope protector of the character described, a body portion having a double-tapered slot extending the full length thereof, and adapted to fit over the cable; a double-tapered removable wedge to conform to the tapered slot adapted to fit in the latter; and a tapered locking-key to fit in an opening formed through the side of the body portion and through said wedge; as, and for, the purpose set forth.

3. In a wire-rope protector of the character described, a body portion having a double-tapered slot extending the full length thereof, and adapted to fit over the cable; a double-tapered removable wedge to conform to the tapered slot, adapted to fit in the latter; a tapered locking-key to fit in an opening formed through the side of the body portion and through said wedge; and means whereby the wedge may be removed; as, and for, the purpose set forth.

4. In a wire-rope protector of the character described, a body portion having a double-tapered slot extending the full length thereof, and adapted to fit over the cable; corrugations formed in the rear wall of said slot; a double-tapered removable wedge to conform to the tapered slot, adapted to fit in the latter; a groove formed in the inner edge of said wedge; a tapered locking-key to fit in an opening formed through the side of the body portion and through said wedge; and means whereby the wedge may be removed; as, and for, the purpose set forth.

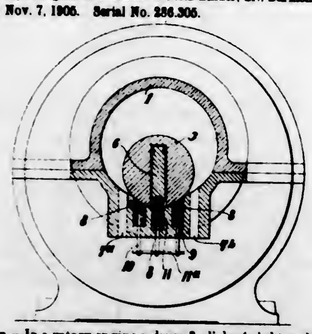
5. In a device of the character described, a body portion having a groove to receive a cable, and a filler for the groove binding against the cable and means for holding the filler against displacement.

6. In a device of the character described, a body portion having a groove to receive a cable, and a filler for the groove binding against the cable and means extending transversely of the body for holding the filler against displacement.

7. In a device of the character described, a body having a wedge-slot, adapted to receive a cable and a wedge fitting within said slot and bearing against said slot and said wedge having notches on its outer surface.

8. In a device of the character described, a body having a wedge-slot adapted to receive a cable, and a wedge fitting within said slot and bearing against the cable, and an eye carried by the wedge.

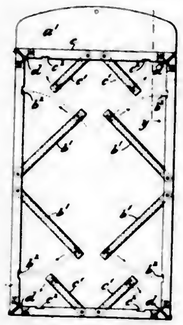
812,414. **ROTARY ENGINE.** FRITZ EGERSDÖRFER. Wiesbaden, Germany, assignor of one-half to Fritz Linder, Sr., Barmen, Germany. Filed Nov. 7, 1905. Serial No. 286,305.



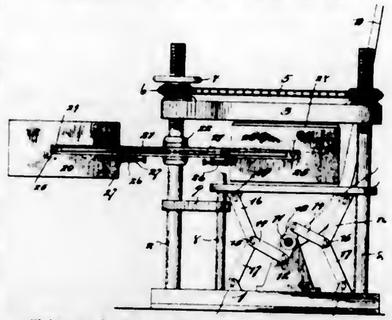
Claim.—In a rotary engine a drum 3, disks 4 right and left of the same, a cylinder 1 and covers 2 inclosing said drum and disks, shafts 5 connected to the disks 4 and journaled in said covers 2, a piston-plate 6 held radially movable in the drum 3, in combination with tightening-bars 8 embedded in corresponding grooves in the cylinder 1, pressure-bars 11 below said tightening-bars 8, bolts 10 fixed to said bars 11 and passing to the outside of the cylinder 1, springs 9 laid round said bolts and pressing the pressure-bars 11 together with the tightening-bars inwardly against the drum 3, cross-bars 11^a holding the bolts 10, and the bars 11 together, the whole as described and illustrated and for the purpose set forth.

812,415. **FRAME AND BOARD FOR DISPLAYING ADVERTISING BILLS, PICTURES, &c.** ARTHUR BRETT. Ealing, England. Filed June 19, 1905. Serial No. 265,960.

Claim.—An improved advertising-frame having in combination a wood back, two side pieces secured to the back, and two end pieces hinged to the fixed side pieces, the hinges being secured beneath the raised flush surface of the said side and end pieces at the corners of the frame, the end pieces being adapted to move upon their hinges outwardly and inwardly in relation to the back to freely admit or remove a bill or poster, and radial arms carrying elastic pads to smooth out and clamp the said bill or poster flat against the wood back, substantially as and for the purpose herein described and shown by the drawings.



812,416. **PRESS FOR CONCRETE BUILDING-BLOCKS.** JOHN A. FERGUSON. Denver, Colo. Filed Oct. 12, 1905. Serial No. 282,406.



Claim.—1. In a press, the combination with the presser-plate and its actuating means, of an eccentrically-mounted mold-box and a support therefor mounted for movement above said presser-plate and to swing in a horizontal plane into and out of operative relation to said presser-plate.

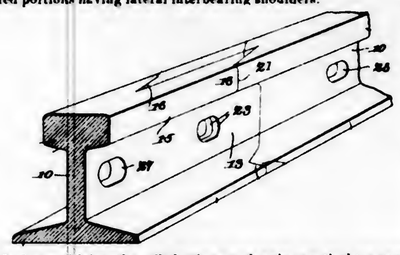
2. In a press, the combination with the presser-plate and its actuating means, of a mold-box eccentrically pivoted to automatically swing through an arc of more than ninety degrees and a support therefor mounted to swing in a horizontal plane into and out of operative relation to said presser-plate, said mold-box being mounted for inversion.

3. In a press of the character described, the combination with the bed, of posts rising therefrom, an adjustable upper plate on said posts, a presser-plate guided vertically on a portion of said posts, a shorter vertical guide rising from the bed and braced from another of said posts, a mold-support mounted for rotation on said last-named post and adapted to swing above said guide and between said plates and means for raising and lowering said presser-plate.

4. A press and a mold mounted to swing horizontally into and out of the press, said mold being eccentrically pivoted to swing beyond a vertical center by gravity.

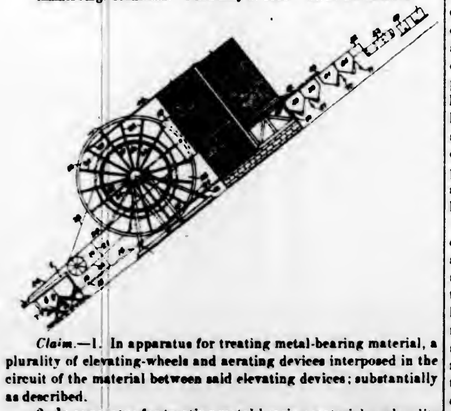
812,417. **RAILWAY-RAIL JOINT.** ELI T. FORRESTER. Denver, Colo. Filed Dec. 9, 1905. Serial No. 291,123.

Claim.—1. In a rail-joint, the rails having overlapping vertical tongues extending from their adjacent ends, each tongue being an extension of one-half of the vertical web one-half of the tread and one-half of the tie-flange of the respective rails, with the terminals of the tongues scarfed for a distance and with recesses at the inner ends of the tongues corresponding to and adapted to respectively receive the scarfed terminals of the tongues when the rails are disposed end to end, the outer ends of the recesses and the inner ends of the scarfed portions having lateral interbearing shoulders.



2. In a rail-joint, the rails having overlapping vertical tongues extending from their adjacent ends, each tongue being an extension of one-half of the vertical web one-half of the tread and one-half of the tie-flange of the respective rails with the terminals of the tongues scarfed for a distance and with recesses at the inner ends of the tongues corresponding to and adapted to respectively receive the scarfed terminals of the tongues when the rails are disposed end to end, the outer ends of the recesses and the inner ends of the scarfed portions having lateral interbearing shoulders and clamp-bolts uniting the overlapping tongues.

812,418. **APPARATUS FOR TREATING SLIMES, &c., FOR THE RECOVERY OF THE PRECIOUS METALS.** CHARLES GLUYAS. Johannesburg, Transvaal. Filed May 3, 1905. Serial No. 256,676.



Claim.—1. In apparatus for treating metal-bearing material, a plurality of elevating-wheels and aerating devices interposed in the circuit of the material between said elevating devices; substantially as described.

2. In apparatus for treating metal-bearing material, a plurality of elevating devices, and aerating devices comprising a plurality of superposed launders interposed in the circuit of the material between said elevating devices; substantially as described.

3. In apparatus for treating metal-bearing material, a plurality of elevating devices, and aerating devices comprising a plurality of superposed helically-disposed launders interposed in the circuit of the material between said elevating devices; substantially as described.

4. In apparatus for treating metal-bearing material, a plurality of elevating-wheels arranged side by side, and aerating devices interposed in the circuit of the material between said elevating-wheels; substantially as described.

5. In apparatus for treating metal-bearing material, an elevating device comprising a wheel having a plurality of sets of elevating-buckets, means for driving said wheel, and means for conveying the material to said sets of buckets in succession; substantially as described.

6. In apparatus for treating metal-bearing material, an elevating device comprising a plurality of wheels, each provided with a plurality of sets of elevating-buckets, means for driving said wheels, and means for conveying the material in succession to said several sets of buckets; substantially as described.

7. In apparatus for treating metal-bearing material, an elevating device comprising a plurality of wheels, each provided with a plurality of sets of elevating-buckets, means for driving said wheels, means for conveying the material in succession to said several sets of buckets, and aerating devices interposed in said conveying means; substantially as described.

8. In apparatus for treating metal-bearing material, an elevating device comprising a plurality of wheels, each provided with a plurality of sets of elevating-buckets, means for driving said wheels, means for conveying the material in succession to said several sets of buckets, and aerating devices comprising superposed launders interposed in said conveying means; substantially as described.

812,419. **FILE OR HOLDER FOR PAPERS AND LEAVES.** ALFRED C. HAFELY. Brooklyn, N. Y. Filed Aug. 21, 1901. Serial No. 73,780.

Claim.—1. In a temporary binder for leaves the combination of a pair of covers the upper cover having right-angular portions located on either side thereof the lower cover also having right-angular portions on either side thereof which overlap and are located within the right-angular portions of the upper cover, the said right-angular portions of the lower cover having open slots, threaded studs supported in the overlapping portions of the upper cover and movable along the said open slots in the lower cover, nuts located on the said studs for adjusting the distance between the covers.

2. In a temporary binder for leaves the combination of a pair of covers, the upper cover having a right-angular portion located on each side and at the end of the said upper cover, the lower cover also having a right-angular portion located at each side and at the end thereof which overlaps and is located within the right-angular portion of the upper cover, the said right-angular portions of the lower cover having open slots, threaded studs supported in the overlapping portions of the upper cover and movable along the said open slots in the lower cover, nuts located on the said studs for causing the overlapping portions to frictionally engage with each other at any point along the said slots, pins carried by the upper cover and sockets supported on the lower cover for receiving the said pins whereby the leaves may be easily inserted or removed from the said holder.

3. In a temporary binder for leaves the combination of a pair of covers connected together by a flexible back, the upper cover having a right-angular portion located on each side and at the end of the said upper cover, the lower cover also having a right-angular portion located at each side and at the end thereof which overlaps and is located within the right-angular portion of the upper cover, the said right-angular portions of the lower cover having open slots, threaded studs supported in the overlapping portions of the upper cover and movable along the said open slots in the lower cover, nuts located on the said studs for causing the overlapping portions to frictionally engage with each other at any point along the said slots, pins carried by the upper cover and sockets supported on the other cover for receiving the said pins whereby the leaves may be easily inserted or removed from the said holder.

812,420. **BURGLAR-ALARM.** FREDERICK C. HARRIMAN, Yonkers, N. Y. Filed Sept. 24, 1904. Serial No. 225,739.

Claim.—1. A detonating burglar-alarm comprising a base, a hammer pivoted upon said base and having an arched back, and a spring fixed at one end upon said base in rear of said hammer and inclining upwardly thereto and resting upon said arched back; means being provided for retaining the hammer in its raised position, the hammer being releasable by downward pressure upon the spring, and the tension of the spring caused by such pressure being effective to cause the hammer to strike.

2. A detonating burglar-alarm comprising a sheet-metal base having downwardly-turned prongs and upwardly-turned ears which

said point of body connection, and a spring secured at its middle to the cross-bar of the shaft and from the ends of which the forward and

3. In a nut-tapping machine, the combination with a tap and a reciprocating nut-blank holder, of a feed-table having at the end a

3. Means to replenish the air-chamber of a pump with air comprising two chambers disposed one above the other, a partition

2. A detonating burglar-alarm comprising a sheet-metal base having downwardly-turned prongs and upwardly-turned ears which form a pocket for holding a detonator, a hammer pivoted between said ears, and a spring secured at its rear end to said base and inclining upwardly and forwardly and bearing upon said hammer; means being provided for enabling said spring to hold said hammer cocked, and the construction being such that downward flexure of the spring releases the hammer and causes it to strike.

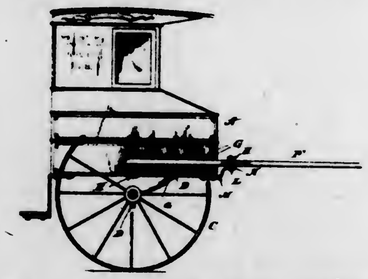
3. A detonating burglar-alarm comprising a strip of sheet metal having at each end a pair of downwardly and forwardly turned prongs and near its forward end a pair of upwardly-turned ears which form a pocket for the reception of a detonator, an arched hammer pivoted between said ears and provided upon its tip with a boss, and a spring attached at its rear end to the rear of said strip and inclining upwardly and forwardly and having a cupped portion to fit over said boss for holding the hammer when cocked, the spring being of such a length that its tip rides down along the arched back of the hammer while the latter is striking.

4. A burglar-alarm comprising the combination of a base; a hammer pivotally mounted therein; and a spring secured at its lower end to said base and having its upper free end overlapping the upper free end of said hammer in the latter's cocked position, the upper free end of said spring being formed with a retaining-recess for holding said hammer in cocked position.

5. A burglar-alarm comprising the combination of a base provided with retaining means; a hammer pivotally mounted in said base and actuated by a flat spring; and said flat spring one end of which is secured to the base and the other end of which overlaps and retains said hammer in cocked position; said hammer being released by pressure upon said spring and driven by said spring after such release.

6. In combination, a door; a base; a hammer mounted in said base; and an inclined spring-arm the lower end of which is secured to said base and the upper end of which is formed to engage and retain in cocked position said hammer; said door and base being movable relatively to each other, and said spring-arm being in the path of travel of said door and actuated directly by the pressure of said door to release and drive said hammer against said base.

812,421. **TWO-WHEELED VEHICLE.** FRANCIS M. HARRINGTON, Peoria, Ill., assignor to The Harrington Manufacturing Company, Peoria, Ill., a Corporation of Illinois. Filed May 22, 1905. Serial No. 261,706.



Claim.—1. In a two-wheeled cart, the shafts, a spring secured at one end to each side member thereof substantially as shown, the opposite ends of the springs secured to the cart-axle, the cart-body suspended between the said rear extremities and secured thereto, a spring secured at the middle of its length to the connecting-bar of the shafts at right angles to the said side members thereof, the free flexing ends of the spring having connection with the front of the body.

2. In a two-wheeled vehicle the body thereof, the shafts therefor having the body located therebetween, said body having attachment with the rear ends, a spring secured at one end to each shaft, the other ends of the springs having attachment with the axle, and a third spring secured at its middle to the cross-bar of the shafts forward of the body its ends having connection with said body for yieldingly supporting the forward end thereof.

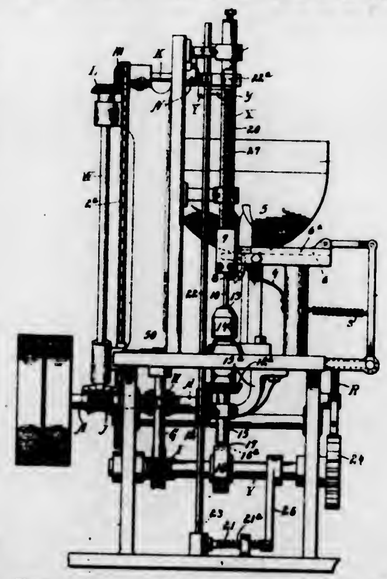
3. In a two-wheeled vehicle, the shafts, the body located therebetween and secured substantially at its middle to the end of each, a spring secured to each shaft forward of the point of connection with the body, the rear ends of the springs secured to the axle beneath the said point of body connection, and a spring secured at its middle to the cross-bar of the shaft and from the ends of which the forward end of the body is hung substantially as shown.

4. In a two-wheeled vehicle the shafts, the cart-body secured to and between and balanced upon the rear ends thereof, the axle being located below the point of connection of the shafts and body, a spring secured to each shaft member forward of the axle and extending to said axle and secured thereto, and a spring on the cross-bar of the shafts forward of the body, the latter being suspended at its forward end from the free end of said spring.

5. In a two-wheeled vehicle, the shafts, the body located between the rear ends thereof and secured thereto at its center of gravity, the axle just below the point of connection, a half-spring secured at one end to each shaft member and at the other to the axle, a spring secured at its middle to the connecting-bar of the shafts forward of the body and parallel with the axle, and pivotal connection between the spring ends and the said body.

6. In a two-wheeled vehicle, the shafts, the body located therebetween, and secured substantially at its middle to the end of each, a spring secured to each shaft forward of the point of connection with the body, the rear ends of the springs secured to the axle beneath the said point of body connection, a third spring secured at its middle to the cross-bar of the shafts at right angles to the latter, members attached to the body and extending forward therefrom and having loose connection with the free flexing ends of the said third spring substantially as described.

812,422. **NUT-TAPPING MACHINE.** JESSE J. HARRIS, Berea, and ANDREW A. PRIOR, Cleveland, Ohio, assignors of one-half to Thomas Reid, Cleveland, Ohio. Filed Apr. 3, 1905. Serial No. 253,408.



Claim.—1. In a nut-tapping machine, the combination with a tap having an extended shank to receive a plurality of nuts passed over the tap, of a chuck normally engaging the end of the shank, a shaft having a notched cam thereon, a plunger which supports the chuck and is supported on the cam and adapted to drop into the notch and release the chuck during one of a series of strokes, a reciprocating blank-holder arranged to force blanks over the tap and onto the shank, and having jaws operating to grip the tap at its front end when the chuck is released, feed mechanism to deliver blanks to the holder, and means to arrest the feed when the tap is gripped by said jaws.

2. In a nut-tapping machine, the combination with a tap and a reciprocating nut-blank holder which forces blanks upon the tap, of a feed-table, and a yielding feed-support for the blanks, attached to the table and located between the tap and holder and arranged to swing out of the way when the holder advances.

3. In a nut-tapping machine, the combination with a tap and a reciprocating nut-blank holder, of a feed-table having at the end a pivoted blank-support having a forked end projecting between the tap and the holder and in the way of the latter, and constructed to support a blank over the point of the tap and to swing out of the way of the holder as it advances.

4. In a nut-tapping machine, the combination with the tap, and the reciprocating holder arranged for forcing blanks thereon, of the feed-table having at the end a swinging blank-support projecting between the tap and holder and arranged to yield when the holder advances, and the slide upon the table, for feeding blanks onto said support.

5. In a nut-tapping machine, the combination with a tap, of a reciprocating tubular plunger having a blank-holder at the end, a block in said plunger, springs between said block and the ends of the plunger, and a crank connected to said block.

6. In a nut-tapping machine, the combination with a reciprocating blank-holder constructed to force blanks over a tap, of feed mechanism feeding blanks to the holder, means to arrest the feed during one of a series of strokes, and means to simultaneously strip the nuts from the tap.

7. In a nut-tapping machine, the combination of a tap, means to support and rotate the same, a plunger having a blank-holder constructed to force nuts onto the tap, jaws carried by the plunger and arranged to grip the tap, rods normally slidable with the plunger and having a connection with the jaws, to close the same when the movement of the rods is stopped, and means to stop the movement of the rods at predetermined times.

812,423. **MEANS TO REPLENISH THE AIR-CHAMBERS OF PUMPS WITH AIR.** HENRY T. HAZARD, Los Angeles, Cal., assignor of one-half to Albert Hobercht, Ensenada, Mexico. Filed Oct. 5, 1904. Serial No. 227,273.

Claim.—1. Means to replenish the air-chamber of a pump with air, comprising a main air-chamber and a supplementary chamber below the same, a partition therebetween, a port in said partition and a port in the bottom of the supplementary chamber and valvular means to alternately open and close said ports.

2. A pump provided with a main air-chamber and a supplementary chamber divided by a partition, a valve-controlled port in said partition for the passage therethrough of air and water, a valve-controlled port in the supplementary chamber for the passage of air and water, and valvular means to alternately open one port and close the other.

3. Means to replenish the air-chamber of a pump with air comprising two chambers disposed one above the other, a partition between said chambers, a port therein, a port in the bottom of the bottom chamber, and valves controlling said ports, the said valves being workably connected together and adapted one to be closed as the other is opened and means to open and close said valves.

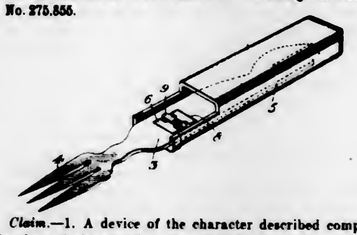
4. In a pump having an air-chamber, the herein-described means to replenish the chamber with air comprising the supplementary chamber F, a partition G between the chambers, a port G' therein, a port I' in the bottom of the supplementary chamber and means to control said ports comprising the valves J and K, the valve J secured to the swinging lever M and the swinging lever M and means to swing said lever.

5. In an air-chamber for a pump provided with a supplementary chamber below, the said chambers being divided by a partition having a port therein and a port in the bottom of the supplementary chamber, the herein-described swinging lever pivotally mounted in the supplementary chamber and carrying at one end a valve adapted to control the port between the chambers and at the other end a valve adapted to control the port in the bottom of the supplementary chamber, in combination with means to operate said lever.

6. In a pump having a main air-chamber and a supplementary chamber of the character herein described, the herein-described float disposed in the main air-chamber, adapted when in its depressed position to lock the valves controlling the port in the partition between the chambers and the port in the bottom of the supplementary chamber, and prevent the operation of the valves and to unlock said valves when in its elevated position.

7. In combination a pump-cylinder, an air-chamber thereon a supplementary chamber below the air-chamber, a port between the chamber and a port in the bottom of the supplementary chamber and valvular means to control said ports in combination with means to operate said valvular means.

812,424. **COMBINED KNIFE, FORK, CAN-OPENER, AND SAW.** CHARLES HELLMUTH, New York, N. Y. Filed Aug. 26, 1905. Serial No. 275,855.



Claim.—1. A device of the character described comprising a casing formed of separable sections, blocks secured in said sections, buttons pivoted on said blocks and implements embodying plates having slots adapted to be engaged by said blocks, substantially as described.

2. A device of the character described, comprising a casing formed of separable sections having overlapping ends, blocks secured in said sections, buttons pivoted on said blocks and implements embodying plates having slots adapted to be engaged by said blocks, substantially as described.

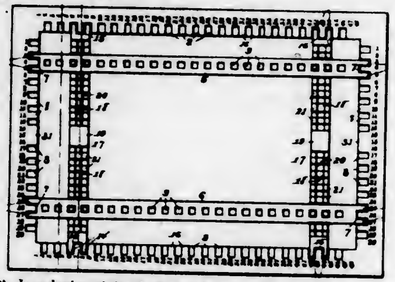
3. A device of the character described comprising a casing formed of separable sections having overlapping ends and slots in said ends, blocks secured in said slots, buttons pivoted on said blocks, and implements having slots adapted to be engaged by said blocks, substantially as described.

4. A device of the character described comprising a casing formed of separable sections having overlapping ends and slots in said ends, blocks secured in said slots, buttons pivoted on said blocks, and implements embodying plates having slots adapted to be engaged by said blocks, and plates for securing said blocks, substantially as described.

5. A device of the character described comprising a casing formed of separable sections having overlapping ends and slots in said ends, notched blocks secured in said slots, buttons pivoted on said blocks, and implements embodying plates having slots adapted to be engaged by said blocks, substantially as described.

812,425. **BOOK AND JOB CHASE.** OSCAR HOWARD, Wheeling, W. Va., assignor of one-half to Richard Robertson, Wheeling, W. Va. Filed Apr. 8, 1905. Serial No. 254,480.

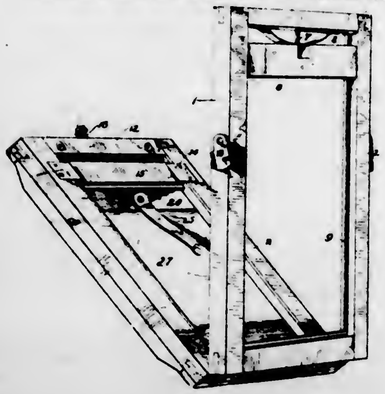
Claim.—1. In a device of the character described, a chase having a plurality of spaced recesses along the inner edges of its sides and ends, the recesses in the ends being inwardly inclined at opposite sides of a point intermediate the extremities thereof, a top stick and a foot-stick extending from one end of said chase to the other, the ends of said sticks provided with projections for interlocking engagement with said inclined recesses, end sticks extending from one side of said chase to the other and having their ends provided with projections for interlocking engagement with the recesses in said sides, spaced perforations in all of said sticks, and spaced studs carried by the engaging faces of said sticks, the studs on the end sticks being adapted for interlocking engagement with the perforations in the top stick and the foot-stick, and vice versa.



2. In a device of the character described, a chase having a plurality of spaced recesses along the inner edges thereof, a top stick, a foot-stick and end sticks, all said sticks having ends adapted for interlocking engagement with the recesses in said chase, said top stick and foot-stick each provided with a longitudinal channel in its under face, spaced perforations opening into said channels from the upper faces of said sticks, a longitudinal row of spaced vertical studs carried by each of the last-mentioned sticks at each side of the channel therein, each of said end sticks provided with a channel in its upper face, spaced perforations opening into said channels from the under faces of said end sticks, and a row of spaced vertical studs carried by each of said end sticks at each side of the channel therein, all of said sticks being adapted to be adjusted with relation to the size of the form to be embraced thereby with studs of the top stick and foot-stick in engagement with perforations in said end sticks, and vice versa.

3. In a printer's chase, the combination with a frame provided with spaced recesses in its inner edge, of a top stick, foot-stick and two end sticks having projections in their ends for engaging the recesses in the frame, said sticks provided on their opposing faces with alternating spaced recesses and studs, the recesses and studs carried by the top stick and the foot-stick being adapted for interlocking engagement respectively with the studs and recesses carried by said end sticks, and vice versa.

812,426. **PRINTING-FRAME.** ALFRED J. JARMAN, New York, N. Y., assignor to Paragon Photo-Chemical Company, New York, N. Y., a Corporation of New York. Filed June 8, 1905. Serial No. 264,284.



Claim.—1. In a printing-frame, the combination of a positive-plate holder and a negative-plate holder, said negative-plate holder comprising upper lower, and side bars, a spring-influenced cross-bar adapted to be reciprocated between said side bars and a removable back wall having an outwardly-extending spring upon its inner face, securable within said positive-plate holder.

2. In a printing-frame, the combination of a positive-plate holder and a negative-plate holder, said negative-plate holder comprising upper lower, and side bars, a cross-bar adapted to slide between said side bars means depending from the upper bar to limit the downward motion of said cross-bar and a removable back wall having an outwardly-extending spring upon its inner face, securable within said positive-plate holder.

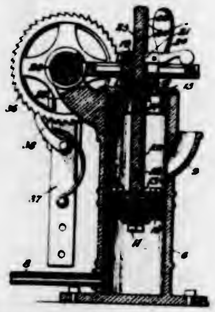
3. In a printing-frame, the combination of a positive-plate holder and a negative-plate holder, said negative-plate holder comprising upper lower, and side bars, a cross-bar adapted to slide between said side bars, a spring coacting with said cross-bar and having a normal tendency to force said cross-bar downwardly and a removable back wall having an outwardly-extending spring upon its inner face, securable within said positive-plate holder.

4. In a printing-frame, the combination of a positive-plate holder and a negative-plate holder, a removable back wall securable within said positive-plate holder, and an outwardly-extending spring secured to the inner face of said back wall.

812,427. **WHEEL-TIRE FOR AUTOMOBILES.** HERMAN KERNSOOD, Baltimore, Md., and HARRY A. TAYLOR, New York, N. Y. Filed July 3, 1905. Serial No. 268,196.

Claim.—The combination with a sheet-metal rim, strips secured to the rim with washers interposed between the strips and the rim, convolute springs extending transversely of the rim and having loose sliding connection between the rims and the strips, a transversely-bent strip 5 fitted over the several springs and a rubber tire inclosing said strip and springs and secured at its edges in edges of the rim.

812,428. **LUBRICATOR.** OLE O. KITTLESON, Lee, Ill. Filed May 15, 1905. Serial No. 260,433.



Claim.—1. The combination with a holder, of a piston operating therein, a support, a stem connected to the piston and having a threaded engagement with the support, operating means including a device rotatable about the stem, a dog for holding said device and stem against relative movement and permitting the sliding movement of the stem through the device, and means for automatically operating the dog to disengage the stem and driving device to permit the rotation of the latter with respect to the former when said stem has reached a predetermined position.

2. The combination with a holder, of a piston operating therein, a stationary support, a stem connected to the piston and having a threaded engagement with the support, an operating-wheel rotatable about the stem, a dog carried by the wheel for holding said wheel against relative rotation and permitting the sliding movement of the stem through the wheel, and means carried by the stem and engaging the dog when said stem has reached a predetermined position to unlock the wheel from the stem and permit the free rotation of said wheel.

3. The combination with a holder, of a piston slidable therein, a cap secured upon the upper end of the holder, a stem connected to the piston and having a threaded engagement with the cap, an operating-wheel mounted on the cap and rotatable upon the stem, said stem also being slidable through the wheel and being provided with a longitudinally-disposed keyway, a dog pivoted upon the wheel and normally engaged in the keyway to prohibit the relative rotation of the wheel and stem to permit the sliding movement of said stem, said stem having a shoulder located at the upper portion of the keyway and arranged to engage the inner end of the dog and move it out of said keyway when the stem moves downwardly to a predetermined position.

4. The combination with a holder, of a piston operating therein, a stationary support, a stem connected to the piston and having a threaded engagement with the support, said stem having a keyway, a wheel having a bore that slidably receives the stem, said wheel being rotatable about the stem, a worm engaging the wheel for operating the same, a dog movably mounted on the wheel and normally engaging in the keyway to prevent the rotation of said wheel about the stem, means located in the keyway for moving the dog out of the same when the stem reaches its predetermined position, said stem having a supporting-shoulder located in the keyway above said means, said dog being arranged to rest upon the shoulder in the keyway and support the wheel out of engagement with the worm, and a handle carried by the wheel.

5. The combination with a holder, of a piston operating therein, means for moving the piston including a worm-wheel, spaced journal-bearings located at one side of the wheel, a shaft passing through the bearings, means connected to the shaft for rotating the same, a worm loosely journaled on the shaft between the bearings and meshing with the worm-wheel, a clutch connection between one end of the worm and the shaft, a coiled spring bearing against the other end of the worm for yieldingly maintaining the clutch connection, said spring being mounted on the shaft and passing through the adjacent bearing, and means adjustably mounted on the shaft outside the bearing and engaging the spring to vary the tension thereof.

6. The combination with a holder, of a piston operating therein, means for moving the piston including a worm-wheel, spaced journal-bearings located at one side of the wheel, a shaft passing through the bearings, a ratchet-wheel secured to the shaft on the outer side of one of the bearings, a worm loosely journaled on the shaft between the bearings and meshing with the worm-wheel, a clutch connection between the shafts and the end of the worm that is adjacent to the ratchet-wheel, and means for yieldingly maintaining said clutch connection, said means bearing against the other end of the worm and passing through the adjacent bearing.

7. The combination with a holder, of a rotatable actuating device having an axial bore, a plunger operating in the holder and having a stem longitudinally slidable in the bore, a key movably associated with the stem and actuating device to prevent their relative rotation and permit the said sliding movement of the stem, means normally engaging the actuating device for operating the same, said device being slidable upon the stem out of operative engagement with the operating means and thus constituting means for manually operating the stem, and means carried by the stem and engaged by the key for holding the actuating device out of engagement with the operating means to permit the said manual operation of the stem.

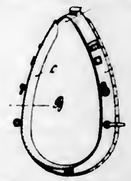
8. The combination with a holder, of a stationary element associated therewith, a rotatable actuating-wheel having an axial bore, a plunger slidably mounted in the holder, a rotatable stem having a threaded engagement with the stationary element and having a longitudinally-sliding movement through the bore of the wheel, a key movably mounted on the wheel and having a slidable engagement with the stem to hold said stem and wheel against relative rotation, operating means engaging the wheel for rotating the same, said wheel having a handle and being movable on the stem to a position out of engagement with the operating means, and said stem having means engaged by the key to maintain said wheel out of such engagement to permit the manual rotation thereof.

812,429. **NUT-LOCK.** JAMES W. KOCH, Reynolds, Pa. Filed Aug. 16, 1904. Serial No. 220,936.

Claim.—1. A device of the character described, comprising in combination with a bolt having a threaded shank provided with a bore, a nut, said nut having a bore for coöperating with the bore in the bolt, and having grooves merging with said nut-bore at its ends, and a wire key passing through said bore and adapted to have its ends bent over into said grooves, and a ring integrally formed with said nut, said ring having a larger internal diameter than the nut axial bore and a lesser external diameter than the diameter of the nut, for the purposes described.

2. In combination with a rail and the fish-plates having alining apertures, a bolt passing therethrough, one of said fish-plates having countersunk portions at the nut-receiving end of the bolt, a nut having a threaded engagement with said bolt, a ring integrally formed with the nut projecting from the rear face thereof, the internal diameter of said ring being greater than the diameter of the threaded portion of the nut, and the external diameter of the ring being less than the diameter of the nut, said ring adapted to seat in the countersunk portion of the fish-plate, said nut and said bolt having alining apertures, the apertures of the nut extending diametrically therethrough, said nut having grooves on its opposite faces merging with the apertures of the nut and a key adapted to pass through said nut and bolt apertures and have its ends bent over into the nut-grooves to lock the nut and bolt together substantially as shown and described.

812,430. **COLLAR FOR DRAFT-ANIMALS.** FRANZ LEINEN, Königstein, Germany. Filed Mar. 16, 1904. Serial No. 198,406.



Claim.—A horse-collar composed of two sheet-metal members, one of said members being vaulted, the other thereof being flat, outturned flanges formed on said flat member, a padding adjacent said vaulted member and of less length than said members, and securing means passing through said flanges, vaulted member and padding.

812,431. **FIRING MECHANISM FOR GUNS.** JOHN F. METCS and HERMAN G. JAKOBSSON, Bethlehem, Pa., assignors to Bethlehem Steel Company, South Bethlehem, Pa., a Corporation of Pennsylvania. Filed Jan. 31, 1905. Serial No. 243,563.

Claim.—1. The combination with the mechanical firing devices including a rotatable cam at the breech of a gun, of an operating-handle at one side adjacent to the trunnion, and connections between said handle and said devices whereby said cam can be rotated in one direction only from said handle, substantially as set forth.

2. The combination with the mechanical firing devices including a rotatable cam at the breech of a gun, of an operating-handle supported on the saddle at one side adjacent to the trunnion, and connections between said handle and said devices, whereby said cam can be rotated in one direction only from said handle, substantially as set forth.

3. The combination with the mechanical firing devices at the breech of a gun, of an operating-handle at one side adjacent to the trunnion, and connections including separable toothed gears and means for rotating one of them between said handle and said devices, substantially as set forth.

4. The combination of the firing mechanism at the breech of a gun, a shaft for actuating the same provided with a toothed gear, and toothed driving-gear supported at the side of the gun engaging the gear on the shaft, the gears separable on opening the breech, substantially as set forth.

5. The combination with the firing devices of a gun and swinging carrier supporting the same, of an actuating-shaft and toothed gear, an arm at the side of the gun, a toothed gear carried by said arm adapted to engage the gear on the shaft, and means for turning the

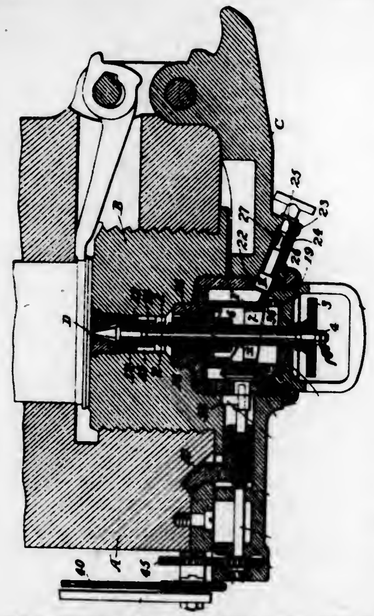
gear on the arm from a position at the side of the gun, substantially as set forth.

and firing-pin of a gun, of a cam rotatable in one direction only for

adjustable to release the plug or both the plug and hub, substantially

hub, of a firing-head supported to slide in and turn with the block,

gear on the arm from a position at the side of the gun, substantially as set forth.



6. The combination with the firing devices, shaft and toothed gear at the breech of a gun, of an operating-handle at the side of the gun, and connections whereby the gear can be driven from said handle in one direction only, substantially as set forth.

7. The combination with the firing devices, shaft and gear at the breech of a gun, of gear engaging that on the shaft, a drive-wheel at the side of the gun connected to turn the latter gear, an operating crank-handle, a spring turning said handle freely in one direction, and means for connecting the handle with the drive-wheel to turn the latter in the opposite direction for firing, substantially as set forth.

8. The combination with the firing devices, shaft and gear at the breech of a gun, of gear engaging that on the shaft, a drive-wheel at the side of the gun connected to turn the latter gear, an operating crank-handle, a spring turning said handle freely in one direction, and a clutch movable on the handle for engaging a shoulder of the drive-wheel, substantially as set forth.

9. The combination with the firing devices, shaft and gear at the breech of a gun, of gear engaging that on the shaft, a drive-wheel at the side of the gun connected to turn the latter gear, and an operating crank-handle, said drive-wheel and handle and gear connected therewith movable longitudinally in respect to the gun, substantially as set forth.

10. The combination with the firing devices, shaft and gear at the breech of a gun, of gear engaging that on the shaft, a drive-wheel at the side of the gun connected to turn the latter gear, an operating crank-handle, said drive-wheel and handle and gear connected therewith movable longitudinally in respect to the gun, and a spring for moving said parts toward the rear, substantially as set forth.

11. The combination with the breech-block of a gun, its carrier and firing devices, of a shaft, connections for operating the firing devices on the turning of the shaft, a toothed gear and means for operating it from the side of the gun, and a toothed gear on the shaft adapted to engage with but separable from the gear connected with operating means at the side of the gun, substantially as set forth.

12. The combination with the breech-block of a gun, its carrier and firing devices, of a shaft, connections for operating the firing devices on the turning of the shaft in one direction, a toothed gear and means for turning it from the side of the gun, and a toothed gear on the shaft adapted to engage with but separable from the gear connected with the operating means at the side of the gun, substantially as set forth.

13. The combination with the swinging carrier, breech-block, and firing-pin of a gun, of a cam rotatable in one direction only for operating the pin, and means for rotating said cam in said direction after the breech is closed, substantially as set forth.

14. The combination with the swinging carrier, breech-block and firing-pin of a gun, of a cam rotatable in one direction only for operating the pin, and means for rotating said cam in said direction after the breech is closed, substantially as set forth.

15. The combination with the firing-pin of a gun, of a rotatable cam for operating the same, a shaft, and gears for rotating said cam after the breech is closed, substantially as set forth.

16. The combination with the firing-pin of a gun, of a rotatable cam for operating the same, a shaft and gears for rotating said cam after the breech is closed, and means at the side of the gun for rotating said shaft, substantially as set forth

17. The combination with the breech-block of a gun, of a firing-pin supported to slide in and turn with said block, a cam for drawing back and releasing the said pin, and means for operating said cam from the side of the gun, substantially as set forth.

18. The combination with the breech-block of a gun, of a firing-pin supported to slide in and turn with said block, a cam for drawing back and releasing said pin, and means for operating said cam from the side of the gun, the parts arranged to draw back the pin by the cam as the pin is rotated in turning the block to open the breech, substantially as set forth.

19. The combination with the breech-block of a gun, of a firing-pin supported to slide in and turn with said block, a cam for drawing back and releasing the said pin, means for operating said cam from the side of the gun, and means for preventing the rotation of the cam during the rotation of the breech-block, the parts arranged to draw back the pin by the cam as the pin is rotated in turning the block to open the breech, substantially as set forth.

20. The combination with the breech-block of a gun, of a firing-pin supported to slide in and turn with said block, a cam for drawing back and releasing the said pin, and means for operating the said cam from the side of the gun, said pin insulated and provided with means for connecting it in an electric circuit, substantially as set forth.

21. The combination of the rotatable breech-block of a gun, a carrier and hollow hub supporting the block, a cam within the hub for operating the pin, and means extending to the side of the gun for operating the cam, substantially as set forth.

22. The combination of the rotatable breech-block of a gun, a carrier and hollow hub supporting the block, an annular cam within the hub for operating the pin, a wing on the shaft of the pin engaging said cam, and means extending to the side of the gun for operating the cam, substantially as set forth.

23. The combination of the rotatable breech-block of a gun, a carrier and hollow hub supporting the block, a double cam within the hub for operating the pin, wings on the pin engaging said cam, and means extending to the side of the gun for operating the cam, substantially as set forth.

24. The combination of the rotatable breech-block of a gun, a carrier and hollow hub supporting the block, an annular cam, a wing on the shaft of the pin engaging said cam, an actuating-shaft supported by the carrier and gears whereby the cam may be rotated by the shaft, substantially as set forth.

25. The combination with the rotatable breech-block, firing-pin, cam, and shaft for actuating the cam, of means for preventing the rotation of the shaft until the breech is fully closed, substantially as set forth.

26. The combination with the rotatable breech-block, firing-pin, cam, and shaft for actuating the cam, of a lip on the shaft, and a recess in the breech-block arranged to permit the passage of the lip only when the breech-block is in firing position, substantially as set forth.

27. The combination with the carrier, hollow hub and rotatable breech-block of a gun, of a firing-pin supported to rotate with and slide longitudinally in the breech-block, a hollow cam-sleeve, and a wing on the firing-pin shaft engaging the cam of the sleeve, the latter supported to turn in bearings of the hub, substantially as set forth.

28. The combination of the rotatable breech-block of a gun, the carrier, a hollow hub supporting the block and detachable from the carrier, a cap detachable from the hub, and a locking device for holding the hub and cap in position on the carrier, substantially as set forth.

29. The combination with the breech-block, firing-pin and carrier of a gun, of a hub supporting said block, and connected detachably with the carrier, a plug detachable from the hub, and a locking device locking the plug, hub and carrier together in one position and adjustable to release the plug or both the plug and hub, substantially as set forth.

30. The combination with the breech-block, firing-pin and carrier of a gun, of a hub supporting said block, and connected detachably with the carrier, a plug detachable from the hub, and a locking-pin P sliding in the carrier and extending through the hub and engaging a recess of the plug, substantially as set forth.

31. The combination of the carrier, breech-block, firing-pin insulated from its stem, means for connecting the same in an electrical circuit, a shaft and means for operating the pin mechanically, and a locking device for locking the parts when firing electrically, substantially as set forth.

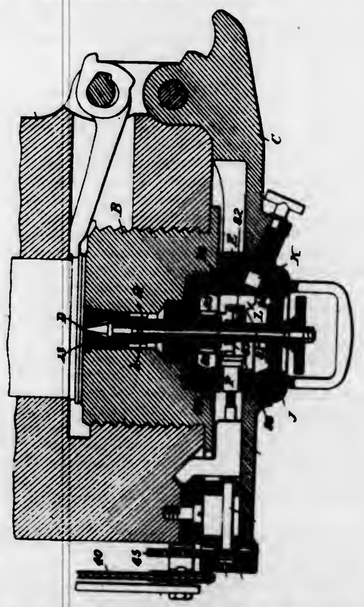
32. The combination with the carrier and firing-pin of a gun, of a breech-block, a hollow hub on the carrier supporting the block and adapted to receive the pin-actuating devices, and a detachable plug closing the end of the hollow hub, substantially as set forth.

33. The combination with the carrier and firing-pin of a gun, of a breech-block, a hollow hub on the carrier supporting the block and adapted to receive the pin-actuating devices, a shaft extending to the side of the gun, and means operated by the shaft to actuate the firing devices, substantially as set forth.

34. The combination with the carrier and firing-pin of a gun, of a breech-block, a hollow hub on the carrier supporting the block and adapted to receive the pin-actuating devices, a shaft extending from the side of the gun into the hub, and means operated by the shaft for actuating the firing devices, substantially as set forth.

35. The combination in a gun-firing mechanism, of a firing-pin having an insulated rod connected with the point, means for connecting said rod in an electric circuit, a cam, shaft and connections for operating the pin mechanically, and means for locking the shaft when firing electrically, substantially as set forth.

812,432. **FIRING MECHANISM FOR GUNS.** JOHN F. MEIGS and HERMAN G. JAKOBSSON, Bethlehem, Pa., assignors to Bethlehem Steel Company, South Bethlehem, Pa., a Corporation of Pennsylvania. Filed Feb. 6, 1905. Serial No. 244,415.



Claim.—1. The combination with the carrier, breech-block, and hollow hub, of a firing-head supported to slide in and turn with the block, a cam connected to the hub and bearing on a projection of the head to retract the firing-pin on turning the block, a sear engaging a shoulder on said head, a shaft extending to the side of the gun, and means for shifting the sear on turning the shaft, substantially as set forth.

2. The combination with the carrier, breech-block, and hollow hub, of a firing-head supported to slide in and turn with the block, a cam connected to the hub and bearing on a projection of the firing-head to retract the firing-pin on turning the block, a sear engaging a shoulder on said head, a shaft extending to the side of the gun, means for shifting the sear on turning the shaft, and means for operating the shaft from the side of the gun, substantially as set forth.

3. The combination of the carrier, breech-block, hollow hub, a cam supported immovably but detachably in said hub, and a firing-head and appliances for operating the same from said cam, substantially as set forth.

4. The combination of the carrier, breech-block, hollow hub having a removable plug, a cam supported immovably but detachably in said hub, and a firing-head provided with a wing for engaging said cam, substantially as set forth.
